THE TREATMENT OF GOUT

PISTANY

RADIO-ACTIVE MUD PACKS

PISTANY SPA REPRESENTATION,

136, Regent St., London, W.1. Tel. Gerrard 9506

Pistany (Czechoslovakia) offers the most effective treatment for the cure of gout.

Special provision is made for the diet of gouty patients in the hotels.

In mild cases a few weeks suffice to relieve the condition but the need for prolonged intermittent treatment often makes a course with Pistany Mud Cubes or Compresses at home, under the patient's own doctor's supervision indispensable for a complete cure.

The method of application is safe and inexpensive for Pistany's sulphur Mud is inert and sterile of mineral content and keeps indefinitely.

Send for interesting Medical and Tourist literature.

SMEDLEY'S

Unrivalled suites of Baths for Ladies and Gentlemen, including Turkish and Russian Baths, Aix and Vichy Douches, Massage and Plombières Treatment, an Electric Installation for Baths and other Medical purposes, Dowsing Radiant Heat, D'Arsonval High Frequency, Diathermy, Nauheim Baths, New Soapless Foam Baths, etc. Special provision for invalids. Milk from our farm of 300 acres. Large Winter Garden. Night Attendance. Rooms well ventilated and all bedrooms warmed in Winter. A large Staff (upwards of 60) of trained Male and Female Nurses, Masseurs, and Attendants.

Telegrams: "SMEDLEY'S, MATLOCK." 'Phone: No. 17.

RAYMOND CRAWFURD, M.D.,
Registrar.

University of Birmingham.

FACULTY OF MEDICINE.

ASSISTANT LECTURER AND DEMONSTRATOR IN ANATOMY.

Applications are invited for the post of Whole-time Assistant Lecturer and Demonstrator in Anatomy. Stipend £300 per annum. Four copies of application, with testimonials, should be sent, not later than Monday, March 10th, to the undersigned, from whom further particulars can be obtained.

The University, C. G. BURTON,
Edmund Street, Secretary.
Birmingham. February, 1930.

Leamington Provident DISPENSARY.

In consequence of the resignation of F. R. SUTTON, Esq., M.D., there will be a vacancy at the end of this Quarter on the Medical Staff of the Leamington Provident Dispensary, and the Committee will appoint a MEDICAL OFFICER in ORDINARY to fill it.

Applications, in writing, for this appointment, accompanied by testimonials, should be addressed to the Chairman, Provident Dispensary, Holly Walk, Leamington Spa, and must be received at the Dispensary on or before Tuesday, March 11th.

Copies of the Rules and particulars can be obtained on application to—

F. H. WACKRILL, Secretary.

Grosvenor Sanatorium, Ashford, KENT.

SECOND ASSISTANT MEDICAL OFFICER (male, single, under 40 years of age) required for three months. Salary £250 with board, lodging, and laundry. Applications, together with copies of recent testimonials, to Dr. J. ABERDEIN MILNE, Medical Superintendent.

City and County of Kingston-upon-Hull.

APPOINTMENT OF MEDICAL SUPERINTENDENT.

The Corporation invite applications for the appointment of a Medical Superintendent of the CITY FEVER HOSPITAL and the SANATORIUM at a commencing salary of £800, rising, subject to satisfactory service, by annual increments of £25 to a maximum of £1,000 per annum, together with housing accommodation, rates, and lighting. The age of candidates is not to exceed 40 years.

At present the Fever Hospital contains 112 beds and the Sanatorium 152 beds, but extensions are contemplated, and it is proposed later to build an Orthopædic Hospital on the site, of which the Medical Superintendent will have administrative charge.

Candidates should either have held an appointment of Medical Superintendent of a Sanatorium with the approval of the Ministry of Health, or should, subsequent to qualification,

(1) Have had at least three years' experience in the practice of their profession,
(2) Have spent in general clinical work a period of not less than 18 months, of which not less than six months have been spent in a hospital as resident officer in charge of beds occupied by general medical or surgical cases, and
(3) Have received special training, for a period of not less than six months, in the diagnosis and treatment of Tuberculosis.

They should further possess a wide clinical knowledge of infectious diseases.

The gentleman appointed, who should be married, will be under the administrative control of the Medical Officer of Health.

As the post is a designated post under the Local Government and Other Officers Superannuation Act, 1922, the successful candidate will be required to undergo a medical examination.

Forms of application, which are obtainable from the undersigned, should be returned so as to be received not later than March 8th.

Health Department, W. M. FRAZER,
Guildhall, Medical Officer of
Hull. Health.
February 18th, 1930.

City and County of Kingston-upon-Hull.

APPOINTMENT OF TUBERCULOSIS OFFICER.

The Corporation invite applications for the post of Clinical Tuberculosis Officer at a commencing salary of £800, rising, subject to satisfactory service, by annual increments of £25 to a maximum of £1,000 per annum. The age of candidates is not to exceed 40 years.

Candidates should either have held a previous appointment as Tuberculosis Officer with the approval of the Ministry of Health, or should, subsequent to qualification,

(1) Have had at least three years' experience in the practice of their profession,
(2) Have spent in general clinical work a period of not less than 18 months, of which not less than six months have been spent in a hospital as resident officer in charge of beds occupied by general medical or surgical cases, and
(3) Have received special training, for a period of not less than six months, in the diagnosis and treatment of Tuberculosis.

The gentleman appointed will rank as a Senior Assistant Medical Officer of Health, and will work under the general administrative control of the Medical Officer of Health.

As the post is a designated post under the Local Government and Other Officers Superannuation Act, 1922, the successful candidate will be required to undergo a medical examination.

Forms of application, which are obtainable from the undersigned, should be returned so as to be received not later than March 8th.

Health Department, W. M. FRAZER,
Guildhall, Medical Officer of
Hull. Health.
February 18th, 1930.

Hertford County Hospital.

Applications are invited for the post of RESIDENT SURGICAL OFFICER. Salary £250 per annum, with board, residence, and laundry.

Candidates should hold the Fellowship of the Royal College of Surgeons.

The appointment is for six months in the first instance.

Applications, with copies of three recent testimonials, should be sent to the undersigned and be received not later than Tuesday, Feb. 25th.

PERCY G. BROOKS, Secretary.

County Borough of Dudley.

MEDICAL OFFICER FOR THE TREATMENT OF VENEREAL DISEASES AND FOR MATERNITY AND CHILD WELFARE WORK.

The Dudley Corporation invite applications for the above post at a salary of £750 per annum. Applicants must be under 40 years of age and must be fully registered Medical practitioners. Experience in modern methods of diagnosis and treatment of Venereal Diseases essential, and a D.P.H. will be considered an additional advantage. When not engaged in the treatment of Venereal Diseases the Medical Officer will be expected to conduct a Maternity and Child Welfare Centre and otherwise assist in the Health Department.

The officer appointed will be for administrative purposes under the Medical Officer of Health.

Applications, stating age, experience, and qualifications, endorsed "Medical Officer," and accompanied by copies of three recent testimonials, must be received by the undersigned not later than February 25th.

Municipal Buildings, GEO. C. V. CANT,
Priory Street, Town Clerk.
Dudley. February 11th, 1930.

Metropolitan Asylums Board.

DARENTH TRAINING COLONY FOR THE MENTALLY DEFECTIVE.

A MEDICAL SUPERINTENDENT is required for duty at the DARENTH TRAINING COLONY, DARTFORD, KENT, in the service of the Metropolitan Asylums Board.

Candidates must be under 40 years of age, unless already in the service of the Board or of the London County Council, and must be registered to practise both in Medicine and Surgery in England. The position is pensionable. Salary £1,000 a year, plus fluctuating temporary additions, making the total commencing remuneration at present about £1,265 a year, with unfurnished house (rates, taxes, and water supply free). Full particulars and conditions of appointment on form of application (on which alone application can be made) obtainable by sending stamped addressed foolscap envelope to the Clerk to the Metropolitan Asylums Board, Victoria Embankment, E.C.4.

Applications must be received by Feb. 28th.

ALLAN POWELL,
Clerk to the Board.

Parish of Stepney.

RESIDENT ASSISTANT MEDICAL OFFICERS.

The Guardians invite applications from duly qualified registered Medical Practitioners for the vacant posts of Resident Assistant Medical Officer at their MILE END HOSPITAL, Bancroft Road, Mile End, London, E.1.

Salary £450 per annum, in addition to the customary residential emoluments of rations, lodging, and washing, valued for the purposes of superannuation at £120 per annum.

Candidates must have previously held a Resident Hospital appointment.

Forms of application and particulars as to duties may be obtained from the Medical Superintendent of the Hospital, or will be forwarded from the undermentioned address upon receipt of a stamped addressed foolscap envelope, and must be returned to me by not later than Saturday, March 1st.

By Order,

Administrative Offices, S. McCLELLAND,
Bancroft Road, Clerk to the
Mile End, E.1. Guardians.
February 11th, 1930.

City of Bradford.

MUNICIPAL GENERAL HOSPITAL, ST. LUKE'S.

HOUSE PHYSICIANS and HOUSE SURGEONS required. Salary in each case £200 per annum, with board and lodgings.

These appointments are for six months, renewable for a further period of six months.

Application forms may be obtained from the Medical Officer of Health, Town Hall, Bradford, and should be returned to him not later than February 28th.

Town Hall, N. L. FLEMING,
Bradford. Town Clerk.
February 5th, 1930.

Edinburgh Hospital for Women AND CHILDREN,

Whitehouse Loan, EDINBURGH.

Applications are invited from qualified Medical Women for the post of JUNIOR RESIDENT SURGEON at the above Hospital. The appointment is for six months from April 1st, with board, residence, and laundry.

Applications, with copies of testimonials, to be received by the Secretary on or before March 12th.

Kent County Council.

ASSISTANT MEDICAL OFFICER (MATERNITY AND CHILD WELFARE).

The Kent County Council invite applications for the post of an Assistant Medical Officer (female). Salary £600 per annum, increasing by £12 10s. increments to £650. Candidates should be not more than 40 years of age.

The person appointed will be required to devote her whole time to the duties of the office, and will be under the administrative control and supervision of the County Medical Officer.

The duties will mainly consist of work in connection with the maternity and child welfare scheme, but will include any other duties allotted to the officer as coming within the purview of the County Health Department.

Preference will be given to candidates who have had special experience in connection with maternity work, and the Diploma of Public Health is desirable.

The appointment is subject to the approval of the Ministry of Health and also to the provisions of the Local Government and Other Officers Superannuation Act, 1922, and will be terminable by three months' notice on either side. The person appointed will be required to pass a medical examination as to physical fitness.

Applications, stating age, qualifications, training, and full particulars of past experience, and accompanied by copies of three testimonials, should be submitted to Dr. A. GREENWOOD, County Medical Officer, Sessions House, Maidstone, not later than February 22th.

No official form of application will be issued, and canvassing will be considered a disqualification.

ALFRED GREENWOOD, M.D.,
Sessions House, County Medical Officer.
Maidstone. February 10th, 1930.

City of Plymouth.

MEDICAL SUPERINTENDENT.

MENTAL HOSPITAL.

The Visiting Committee invite applications for the post of Medical Superintendent of the Plymouth City Mental Hospital, Blackadon, Ivybridge, near Plymouth.

Candidates must be duly registered Medical Practitioners who have had experience in the management of a Mental Hospital.

The salary will be £750 per annum, rising by £50 per annum to £1,000 per annum, and the Committee will provide, in addition, a furnished house at Blackadon (where the Medical Superintendent will be required to reside), and coal, light, laundry, vegetables, and dairy produce free. The total value of these emoluments is estimated, and will be taken for the purpose of the Asylum Officers Superannuation Act, 1909, as being worth £200 per annum.

The person appointed must devote his whole time to the duties of the office, and such duties will include those of Certifying Officer under the Mental Deficiency Acts and also (if required) of Medical Officer in Charge of the Mental Clinic.

Canvassing, directly or indirectly, will be a disqualification.

Forms of application and further particulars may be obtained on application to the undersigned.

Applications to be sent to the undersigned, endorsed "Medical Superintendent, Mental Hospital," on or before March 1st.

Dated this 6th day of February, 1930.

Municipal Offices, R. J. FITTALL,
Plymouth. Town Clerk.

County Borough of Dewsbury.

DEPUTY SCHOOL MEDICAL OFFICER AND DEPUTY MEDICAL OFFICER OF HEALTH.

Applications are invited from duly qualified and registered Medical Practitioners (men or women) for the post of Deputy School Medical Officer and Deputy Medical Officer of Health (Tuberculosis and Child Welfare).

Applicants should have had at least three years' experience since qualification. Experience in Eye work and Refractions is essential. The possession of the D.P.H., and previous experience in School Medical Inspections and the work of a School Clinic, and in Tuberculosis and Child Welfare, will be considered important additional qualifications.

The inclusive salary will be at the rate of £550 per annum. Particulars of the duties and conditions of appointment, together with the application forms, may be obtained from Dr. R. M. GALLOWAY, Medical Officer of Health, Market Place, Dewsbury, to whom all applications, accompanied by copies of not more than three recent testimonials, should be returned, endorsed "Deputy Medical Officer of Health," not later than Friday, February 28th.

Town Hall, HOLLAND BOOTH,
Dewsbury. Town Clerk.
February, 1930.

Willesden Urban District COUNCIL.

HEALTH DEPARTMENT.

APPOINTMENT OF DENTISTS.

The Willesden Urban District Council require the services of Two Dentists.

The duties attached to this post include the Dental Inspection and Treatment of School Children and the Dental Inspection and Treatment of Expectant and Nursing Mothers, and Children under five years of age, and such other duties as the Council or Medical Officer of Health may require to be undertaken.

The Dentists work under the administrative control of the Medical Officer of Health.

The appointments are terminable by a month's notice on either side, is subject to the Council's regulations concerning Officers of the Council, and to the provisions of the Local Government and Other Officers Superannuation Act, 1922. The age of candidates should not exceed 40 years, unless they are at present occupying an established post under the Act.

The successful applicants will be required to pass a medical examination.

Candidates must possess a registrable qualification in Dentistry, and devote their whole time to the duties of the office.

Commencing salary £420, rising by four annual increments to £517 10s., with Civil Service bonus in addition, which bonus fluctuates according to the rise or fall in the cost of living, revision being made every six months—namely, March 1st and September 1st. At the present time the commencing salary and bonus is at the rate of £572 6s. 4d. per annum.

Travelling expenses within the district paid by the Council.

Application forms may be obtained on application by letter (enclosing stamped addressed envelope) to the Medical Officer of Health, Health Department, 54, Winchester Avenue, Kilburn, N.W.6, and should be returned to him duly filled in by applicant, together with copies of three testimonials, not later than Friday, March 7th.

Town Hall, E. A. PRATT,
Dyne Road, Clerk of the
N.W.6. Council.

City of Manchester.

The Public Health Committee of the Corporation require the services of a fully qualified Whole-time Woman MEDICAL OFFICER, experienced in midwifery and children's diseases, to hold (under the direction of the Medical Officer of Health) consultations and infant clinics at the Maternity and Child Welfare Centres of the Manchester Corporation, and (under the like direction) to perform such other duties as appertain to the office.

The salary will be £500 per annum.

A statement of the duties and conditions of office may be had on application, in writing, to the Medical Officer of Health, Civic Buildings, 1, Mount Street, Manchester.

Applications, stating age and experience, and endorsed on the envelope "Medical Officer, Child Welfare," must be sent in addressed to the Town Clerk only, and not to members of the Committee or Council, not later than Saturday, March 1st, and be accompanied by not more than three recent testimonials.

The successful candidate will be required to contribute to the Corporation Superannuation Fund, and to execute their deed of service.

Canvassing in any form, oral or written, direct or indirect, is prohibited.

Town Hall, F. E. W. HOWELL,
Manchester. Town Clerk.
February 11th, 1930.

Birmingham Union.

WESTERN HOUSE.

ASSISTANT MEDICAL OFFICER (Female).

Applications are invited from fully qualified Medical Practitioners for the above appointment. The Institution accommodates 1,800 inmates, embracing all classes except mental defectives.

The person appointed will be required to assist in the general medical work of the Institution and to undertake such other duties as may be assigned to her. The appointment is a whole-time one.

The salary attached to the post, which is non-resident, is at the rate of £500 per annum, without other emoluments. A percentage deduction will be made from the salary for superannuation purposes.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be forwarded so as to reach me not later than Monday, March 3rd.

Canvassing, directly or indirectly, will disqualify.

Union Offices, C. P. BEECH,
Edmund Street, Clerk to the
Birmingham. Guardians.
February 14th, 1930.

Willesden Urban District COUNCIL.

APPOINTMENT OF MEDICAL OFFICER (ASSISTANT, MALE).

A Whole-time Medical Officer (Assistant, male), holding a registrable qualification in Public Health, is required in the Health Department of the Willesden Urban District Council.

The salary will be £600 per annum, rising after three years' satisfactory service by increments of £30 per annum to £750 per annum. No bonus will be paid.

The appointment is subject to the Local Government and Other Officers Superannuation Act, 1922, and no candidate over 40 years of age will be appointed.

Applicants should have had experience in Ante-natal and Maternity work, Diseases of Children, and Infectious Diseases.

Application forms, with full particulars of the appointment, may be obtained from the Medical Officer of Health, Health Department, 54, Winchester Avenue, Kilburn, N.W.6, and must be returned to him not later than 9 a.m. on Saturday, March 7th.

Envelopes containing communications relative to this appointment must have "Medical Officer" written on them on the top left-hand corner.

Town Hall, E. A. PRATT,
Dyne Road, Clerk of the Council.
Kilburn, N.W.6. February, 1930.

County Borough of West HARTLEPOOL.

MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER.

The Council of the County Borough of West Hartlepool invite applications from duly qualified and registered Medical Practitioners holding the Diploma in Public Health for the appointment of Medical Officer of Health and School Medical Officer.

The salary will be £900 per annum, rising by two annual increments of £50 to £1,000 per annum.

The gentleman appointed will be required to devote the whole of his time to the duties of the office, and will not be allowed to engage in private practice. He will be responsible for the performance of all duties now devolving upon the Medical Officer of Health and School Medical Officer, or which may be, in future, assigned to him.

Applications, stating age, qualifications, and experience, accompanied by copies of not more than three recent testimonials, and endorsed "Medical Officer of Health," must reach me not later than Saturday, March 1st.

Town Clerk's HAROLD W. STANTON,
Office, West Hartlepool. Town Clerk.
February 10th, 1930.

Administrative County of LONDON.

The LONDON COUNTY COUNCIL invites applications for a position of DIVISIONAL MEDICAL OFFICER in the Public Health Department. The duties attaching to the position will be chiefly in connection with the Council's Tuberculosis Scheme. Candidates should have special knowledge of all branches of Tuberculosis work. The scale of salary (based on pre-war conditions) is £550 a year, rising annually by £50 to £750 a year. In addition, there is a cost of living bonus, making the total commencing remuneration £715 8s. 9d. a year, with a maximum of £947 8s. 9d. Candidates must not be more than 45 years of age on April 1st, 1930.

Forms of application, containing full details, may be obtained from the Clerk of the Council, The County Hall, Westminster Bridge, S.E.1. A stamped addressed envelope should be enclosed, and forms must be returned by February 25th.

Canvassing disqualifies.

MONTAGU H. COX,
Clerk of the London County Council.

County Borough of Halifax.

RESIDENT MEDICAL OFFICER.

HOSPITAL FOR INFECTIOUS DISEASES.

Applications are invited for the appointment of Resident Medical Officer at the Corporation's Isolation Hospital. Salary £350 per annum, together with board, residence, and laundry.

Applications must be made on a prescribed form which may be obtained from the undersigned, and should be sent, together with copies of not more than three recent testimonials, endorsed "Resident Medical Officer," to the undersigned not later than March 5th.

Canvassing, either directly or indirectly, will be a disqualification.

Town Hall, PERCY SAUNDERS,
Halifax. Town Clerk.
February 7th, 1930.

West London Hospital,
Hammersmith, W.6. (234 Beds.)

Applications are invited for the post of HONORARY MEDICAL REGISTRAR for a period of one year, eligible for re-election annually for a total period of not more than three years. An honorarium at the rate of £100 per annum is attached to the post. The successful candidate must hold no appointments at a General Teaching Hospital during his term of office. The duties include the preparation of the Medical Registrar's Report for the year and the supervision of the records of cases. The candidate appointed must be available as substitute for the Physicians and Assistant Physicians when required, and be prepared to undertake such teaching for the Post-Graduate College as the Board may approve.

Candidates are required to be registered under the Medical Act. Applications, with copies only of testimonials, must reach me not later than Thursday, March 20th. *Candidates must* attend the Meeting of the Medical Council on Friday, March 21st, at 4.45 p.m., and prior to that date call upon and send copies of application *and testimonials* to each member thereof. They must not canvass members of the Board, but nevertheless must send copies of their application and testimonials to each member thereof, and, if so notified, be in attendance at a Meeting of the Board at 5 p.m. on Tuesday, March 25th, when the election will be made.

H. A. MADGE, Secretary.

West London Hospital,
Hammersmith, W.6. (234 Beds.)

Applications are invited for the post of HONORARY OBSTETRIC REGISTRAR. The holder of the post is eligible for re-election annually for a total period of not more than three years. The duties include the preparation of the Obstetric Registrar's Report for the year and the supervision of the records of cases. The candidate appointed must be available as a substitute for the Surgeon and Assistant Surgeon for Diseases of Women and for *emergency operations when required, and be prepared to undertake such teaching for the* Post-Graduate College as the Board may approve.

Candidates are required to be registered under the Medical Act. *Applications, with* copies only of testimonials, must reach me not later than Thursday, March 20th. Candidates must attend the Meeting of the Medical Council on Friday, March 21st, at 4.45 p.m., and prior to that date call upon and send copies of application and testimonials to each member thereof. They must not canvass members of the Board, but nevertheless must send copies of their application and testimonials to each member thereof, and, if so notified, be in attendance at a Meeting of the Board at 5 p.m. on Tuesday, March 25th, when the election will be made.

H. A. MADGE, Secretary.

West London Hospital,
Hammersmith, W.6. (234 Beds.)

Applications are invited for the post of HONORARY ASSISTANT SURGEON. Candidates must be Fellows of one of the Royal Colleges of Surgeons of England, Edinburgh, or Ireland. The successful candidate will be required, in addition to other duties, periodically to deliver Surgical Courses of Lectures to the Nurses and to undertake such teaching for the Post-Graduate College as the Board may approve.

Applications, with copies only of testimonials, must reach me not later than Thursday, March 20th. Candidates must attend the Meeting of the Medical Council on Friday, *March 21st*, at 4.30 p.m., and prior to that date call upon and send copies of application and testimonials to each member thereof. They must not canvass members of the Board, but nevertheless must send copies of their application and testimonials to each member thereof, and, if so notified, be in attendance at a Meeting of the Board at 5 p.m. on Tuesday, March 25th, when the election will be made.

H. A. MADGE, Secretary.

West London Hospital,
Hammersmith Road, W.6. (234 Beds.)

Required, One HOUSE PHYSICIAN, Two HOUSE SURGEONS, and One RESIDENT ANAESTHETIST for six months from April 1st next, subject to one month's notice on either side. Salary at the rate of £100 per annum, with board, lodging, and laundry allowance. Candidates must be registered under the Medical Act. Applications (which must be made on printed forms obtained from me) must reach me not later than first post on Friday, March 7th. Selected candidates will be required to call upon such members of the Medical Staff as directed, to be in attendance at a meeting of the Medical Council on Friday, March 21st, at 3 p.m., and the House Committee Meeting at 3.45 p.m. the same day, when the appointments will be made.

H. A. MADGE, *Secretary.*

East Suffolk and Ipswich
HOSPITAL.

ELECTION OF VISITING STAFF FOR FIVE YEARS, UNDER THE RULES AND REGULATIONS OF THE INSTITUTION.

The Board of Management invites applications for the following officers:

One PHYSICIAN.
Two ASSISTANT PHYSICIANS, with Out-patient days and charge of four beds each.
Two GENERAL SURGEONS.
Three ASSISTANT SURGEONS, with Out-patient days and charge of four beds each.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)
(Founded 1880.)

12, Stratford Place,
Oxford Street, W.1.

Telc. Address: Triform, Wesdo—London.

Telephone: Mayfair {1782 / 1783}

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone:* TEMPLE BAR 1616 (3 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES

who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any practice or partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

No charge is made to Principals for the introduction of Locum Tenens or Assistants.
Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. CAMBS.—Old-established Country PRACTICE, averaging for the past three years over £1,200 p.a. Panel of 870. Visits 5/- upwards, medicine extra. About 30 cases of midwifery from 2 to 3 gns. Nice house, with 2 reception, 6 bedrooms, etc., and garden. Rent on lease £80 p.a. Premium £1,800.
2. PARTNERSHIP.—In a most desirable outlying residential suburb a suitable Partner (University Graduate, experienced, 30 to 35 years of age and married preferred) can acquire a share (producing at first about £1,200 p.a., but larger might be considered, with further shares up to a third at arranged intervals) in an old-established good mixed-class Practice, averaging over £10,000 p.a. Very good house, with ample accommodation, garden, etc., on rental. Premium 2 years' purchase. Short preliminary assistantship essential.
3. PARTNERSHIP.—LONDON, S.W.—PLEASANT RIVERSIDE SUBURB.—A one-sixth share is offered in an old-established mainly better-class Practice, rapidly increasing, and with scope for still further development. Average gross cash receipts for past two years £6,213 (last year £6,662). Panel of over 5,000. Fees 3/6 to 21/-. Mid. 3 to 20 gns. Very good house, with 5 to 6 bedrooms, etc. For sale or might be rented. Premium 2 years' purchase.
4. PARTNERSHIP.—WITHIN 100 MILES OF LONDON.—A one-fourth share can be acquired in a very good non-dispensing mainly better-class Practice, in a large town, at present worked by three partners, who now require further assistance. Gross cash receipts average over £8,500 p.a. Panel of 700. Fees 5/- to 21/-. Suitable house obtainable. Graduate preferred, aged 30 to 35, and experienced in anæsthetics. Premium £4,000.
5. MIDLANDS.—Old-established good mixed-class PRACTICE in beautiful country district near large town. Receipts for last twelve months estimated to be £900, and increasing. Fees 3/6 to 20/-. Excellent house with all conveniences, containing 2 reception, 6 bedrooms, etc. Rent on lease £65 p.a. Premium £1,800.
6. SOUTH-EAST COAST.—PARTNERSHIP.—A one-third share (with increase later) in an old-established non-dispensing non-panel Practice, in favourite residential resort. Gross cash receipts average over £3,000, with good scope. Fees 5/- to 21/-. Good corner house, with 6 bedrooms, etc. Can be purchased or rented. Premium 2 years' purchase. Scope for surgery if desired.
7. LONDON, S.W.—Very old-established chiefly middle-class PRACTICE, rapidly increasing and offering still further scope. Gross cash receipts for the immediate past twelve months approximately £5,000. Panel of about 1,500; could be much increased. Fees from 2/6 to 21/-. Two houses available, on rental. Very suitable for two friends in partnership. Premium 1½ years' purchase.
8. NORTH LONDON.—Old-established middle and working-class PRACTICE, averaging nearly £2,200 p.a. Panel of 1,356 and appointments worth about £500 p.a. Visits 3/6 up. Very little midwifery 2½ to 5 gns. Nice house, in excellent repair, 3 reception, 4 bedrooms, etc., and professional rooms. Rent on lease £65 p.a. Premium £3,500.
9. WITHIN 100 MILES OF LONDON.—PARTNERSHIP.—Third share of old-established mixed-class and increasing Practice in small pleasant market town in an agricultural district. Cash receipts last year over £3,100, including appts. worth £300 and panel with mileage producing £500. Visits 3/6 to 15/-. Opposition slight. Railway station. Compact house (consulting and waiting rooms, 2 sitting, 5 bedrooms, dressing and bathroom, etc.). Garden. Garage. Price, freehold, £900. Premium 2 years' purchase.
10. SUSSEX.—Unopposed old established Village PRACTICE in delightful surroundings, producing about £1,100 p.a., including panel of 545, and capable of considerable increase. Exceptionally charming residence standing in 1¼ acres of well-laid-out garden, tennis court, etc., and containing lounge hall, 2 reception, 7 bedrooms (3 fitted h. & c. water basins, dressing and 2 bathrooms, etc. Central heating. Electric light. Garage. Price, freehold, £3950. Premium £1,650.
11. HOME COUNTY.—Near Sea.—Old-established unopposed Country PRACTICE in pretty district. Receipts last financial year £1,113, including union, etc., £55, and panel 400. Railway station near. Good house in own grounds (about one acre, but more can be had if wished), containing 2 reception, 6 bedrooms, etc. Water laid on and electric light available. Price, freehold, £1,650. Premium £1,625. Educational facilities and sport.
12. PARTNERSHIP.—OXON.—Delightful residential district near good town.—A one-third share (to commence with) in an old-established good mixed-class Practice, averaging for the past three years £1,540, and offering good scope. Panel of nearly 1,000. Fees 3/6 to 21/-. Choice of two houses at rentals of £100 and £50 p.a. Sport of all kinds. Premium 2 years' purchase.
13. SOUTH DEVON.—PARTNERSHIP.—Attractive Town close to sea.—A half share in a very old-established and rapidly increasing mixed general Practice. Average cash receipts for last 3 years £2,727, last year £3,521. Panel of 1,130. Fees 3/6 to 21/-. Good house in its own grounds with ample accommodation. Price freehold £1,900, £1,200 on mortgage. Premium £2,300. Cottage Hospital, and good scope for major surgery.
14. BORDERS OF NORTHANTS AND LINCS.—Unopposed old-established Country PRACTICE, within easy reach of large town, and worth over £1,500 p.a., including panel (with mileage) £675, and appts. about £80. Visits 5/- to 20/-. Suitable house available. Rent £70 p.a., or can be bought. Premium 1½ years' purchase. Held by Vendor, who is retiring, over 30 years. Sport of all kinds.
15. NEAR LIVERPOOL.—Mainly better working-class PRACTICE, producing about £700 p.a., including panel of 854. Fees 2/6 to 5/-. Mid. 3 to 5 gns.; about 20 cases yearly. Suitable house available on rental. Premium £1,000.
16. LIVERPOOL.—Middle and working-class PRACTICE. Receipts for immediate past twelve months £1,247, including panel of 602. Fees from 2/6. Suitable house, with 2 reception, 4 bedrooms, etc. Large garden. Price for leasehold £1,550, of which £1,300 could remain on mortgage. Premium £1,550.
17. LONDON, S.W.—Old-established middle-class PRACTICE, producing over £1,000 p.a., including small panel of 380. Fees 2/6 to 7/6. Mid. lately refused. Good corner house, with ample accommodation. Rent on lease £115 p.a. Premium 1½ years' purchase.
18. SOUTH COAST.—FAVOURITE HEALTH RESORT.—Old-established mixed-class PRACTICE, producing about £1,000 p.a. Small panel of 283. Fees from 2/6. Suitable house, with 3 reception, 5 bedrooms, etc. Large garden. Price for leasehold £1,400, £1,250 on mortgage. Premium £1,200.
19. YORKS.—(North Riding).—Country PRACTICE in beautiful district. Average income over £750, including panel of about 330. Fees 3/6 to 21/-, medicine extra. Nearest opponent 4 miles. Suitable house with 2 reception, 4 bedrooms, etc., and garden of 1 acre. Rent on lease £30 p.a. Prem. 1½ years' purchase, part by instalments.
20. MANCHESTER DISTRICT. — Old-established middle and working-class PRACTICE, worth last year about £700, including panel of 590, and capable of increase. Expenses small. Well-situated house, with 6 rooms in addition to professional rooms. Large garden. Price, freehold, £850. Moderate premium accepted.
21. CHANNEL ISLANDS.—Old-established better and middle-class PRACTICE, averaging about £1,000 p.a., but capable of increase. Fees 5/- to 21/-. Little midwifery. No panel. Large well-situated house with garden. Garage for 3 cars. Very pleasant social conditions. Premium for Practice and house £4,000, of which £1,500 to £2,000 could remain on mortgage.
22. KENT.—Old-established Country PRACTICE, in favourite locality, and within 5 miles of the coast. Income for past 12 months £1,185, and increasing. Visits 5/- to 21/-. Panel of about 380. Appts. worth about £50 p.a. Convenient house, with ample accommodation. Nice garden. Price for freehold £1,800. Premium 1½ years' pur.
23. WITHIN TWENTY MILES OF LONDON.—Old-established good mixed-class PRACTICE, in attractive residential district. Receipts average £1,000 p.a. Panel of nearly 500 and appts. worth £60. Visits 3/6 to 21/-. Very nice house, with all modern conveniences and half acre of garden. Price for freehold £1,800. Premium £1,400.
24. YORKS.—PROSPEROUS LARGE TOWN.—Well-established compact PRACTICE, averaging nearly £1,600 p.a., including panel of 1,400. Fees 3/- upwards. Not much midwifery. Low expenses. Very well situated double-fronted house, 2 reception, 4 bedrooms, etc., and good professional accommodation. Garden. Price for freehold £1,500 (£1,000 on mortgage). Premium 1½ years' purchase.
25. YORKS.—LARGE TOWN.—Old-established mainly working-class PRACTICE, producing over £1,200 p.a., including panel of over 1,400. Fees 2/6 to 5/-. Well-situated house, with good garden. Price £1,500. Premium £1,800.
26. LONDON, S.W.—A HALF SHARE, with succession in about 2 years, is offered after preliminary assistantship in a good mixed-class non-panel Practice, producing last year over £2,300. Fees 5/- upwards. Not much midwifery. Suitable flat or rooms available. Premium 2 years' purchase.
27. CHESHIRE.—Industrial Town within easy reach of Manchester.—Well-established PRACTICE producing £2,600 p.a., with panel of 2,870. Fees 2/6 to 3/6, medicine extra. Good house, with ample accommodation. Price £1,000, or would be rented at £70 p.a. Premium 1½ years' purchase, half down and balance by instalments.
28. SOUTH AFRICA.—HEALTH RESORT (Inland Spa).—Old-established increasing PRACTICE (held over 20 years) on a main line of rail and in a healthy pleasant township much frequented by visitors in the Season. Cash receipts average over £1,750 p.a., including several appts. One opponent. Price for house £1,250, to include furniture, instruments, and motor car (original cost £2,000), and for goodwill £1,250, part by instalments. Efficient introduction. A knowledge of Hydrology would be a big asset.

HOUGH, HOSEASON
AND COMPANY LIMITED,
Pharmaceutical Specialists to the Medical Profession,
MANCHESTER

INTERMEDIATE HOSPITAL IN ANNEXE AT 17, PARK LANE

Helped by an endowment fund, an Intermediate Hospital is now open for suitable general surgical cases at 17, Park Lane, London, W.1. The fees for a room cost now only two guineas a week, interest in the scheme having made possible a further reduction since it was started.

(The whole scheme is an attempt to help people unable to pay ordinary full surgical expenses, and yet at the same time to avoid any semblance of a charity which would be distasteful to such.)

All further particulars can be obtained from the Secretary or Matron at 17, Park Lane.
Telephones: Grosvenor 2312 & 2313.

A TYPICAL SCALE OF REDUCED FEES FOR SURGICAL CASES IN THE ANNEXE CLINIC OF THE HAROLD FINK MEMORIAL HOSPITAL AT 17, PARK LANE.

Hospital Fees, including Nursing, 2 guineas a week (limited to an average stay of 3 weeks)	£6 6 0
Dressings, Theatre Fees, etc.	1 1 0
Assistant Surgeon at operation	4 4 0
Anæsthetic Fee	4 4 0
Surgical Fees for Major Operation (from one-fifth usual charges, according to patient's means)	(say) 21 0 0
(From Thirty-five guineas inclusive fee)	£36 15 0

N.B.—The patient must be recommended as a suitable case for these reduced fees by their own Medical Attendant, who will take charge of the after-treatment while in hospital, and be paid direct by the patient his usual fees for such attendance in addition to the fee as Anæsthetist or Assistant at operation.
When the patient's doctor wishes to arrange a preliminary consultation with the Surgeon-in-Chief (with a view, for example, to a Bismuth Meal, Cystoscopic or X-ray Examination, etc.), all that is necessary is to telephone either the Secretary or Matron, and an appointment will be made. (Proportionately reduced nominal fees only charged therefor.)

All rooms are of course separate, and hold one patient only, there being no wards.
Telephones: Grosvenor 2312 & 2313.

THE MEDICAL JOURNAL is this week 38,500 copies.

J. & A. CHURCHILL

SECOND EDITION. 274 Illustrations, 4 Coloured Plates. 18s., postage 9d.

THE QUEEN CHARLOTTE'S PRACTICE OF OBSTETRICS

By J. B. BANISTER, M.D., C. S. LANE-ROBERTS, M.S., A. W. BOURNE, M.B., L. G. PHILLIPS, M.S., T. B. DAVIES, M.D., L. C. RIVETT, M.C., F.R.C.S.
(Members of the Staff of the Hospital).

"The authors have produced one of the most practical works on obstetrics in the English language. . . . The first edition achieved immediate and well-deserved popularity which is likely to continue."—THE LANCET.

NEW (SECOND) EDITION. 2 Plates and 12 Illustrations. 15s., postage 6d.

A TEXT-BOOK OF BIOCHEMISTRY

For Students of Medicine and Science.

By A. T. CAMERON, D.Sc., F.I.C., F.R.C.S., Professor of Biochemistry, University of Manitoba.

4 Plates. 23 Text-figures. 8s. 6d., postage 6d.

A COURSE IN PRACTICAL BIOCHEMISTRY

By A. T. CAMERON, D.Sc., and FRANK D. WHITE, A.R.T.C., Ph.D.Edin., F.I.C., Asst. Professor of Biochemistry, Faculty of Medicine, University of Manitoba.

THIRD EDITION. 556 Illustrations. 32 Coloured Plates. 36s., postage 1s.

EDEN & LOCKYER'S GYNÆCOLOGY

By T. W. EDEN, M.D., F.R.C.P., and CUTHBERT LOCKYER, M.D., B.S., F.R.C.S., Consulting Physicians, Charing Cross Hospital.

SECOND EDITION. 674 Illustrations. Two Volumes. 28s., postage 1s. 3d

THE SCIENCE AND PRACTICE OF SURGERY

By W. H. C. ROMANIS and P. H. MITCHINER, Surgeons, St. Thomas's Hospital.

"A well-balanced account of the Science and Art of Surgery as practised at the present day. There was room for this textbook, and the authors are to be congratulated upon the production of a very useful and practical manual for the undergraduate student. The price is very moderate."—THE LANCET.

2 Coloured Plates, 181 Text-figures. 25s., postage 9d.

STONE IN THE URINARY TRACT

By H. P. WINSBURY WHITE, M.B., Ch.B., F.R.C.S., Hon. Assistant Surgeon, St. Paul's Hospital for Genito-Urinary Diseases.

SEVENTH EDITION. 2 Vols. 900 Illustrations (43 in Colour). 70s., postage 1s. 3d.

ROWLANDS & TURNER'S OPERATIONS OF SURGERY

"This is probably the most important modern textbook on Operative Surgery published by British Surgeons.
"The volumes are not only safe as a book of reference, but of the greatest value to the general surgeon. The searching and detailed revision which has been carried out in the last edition does great credit to the ability and industry of the authors."—PRACTITIONER.

EIGHTH EDITION. 49 Illustrations. 2 Volumes. 63s., postage 1s. 3d.

TAYLOR'S MEDICAL JURISPRUDENCE

Edited by SYDNEY A. SMITH, M.D.(Edin.), D.P.H., Regius Professor of Forensic Medicine, University of Edinburgh; and W. G. H. COOK, LL.D.(Lond.), of the Western Circuit, Barrister-at-Law.

4 Plates. 5s., postage 3d.

A PRACTICAL GUIDE TO THE SCHICK TEST

AND DIPHTHERIA AND SCARLET FEVER IMMUNISATION

By GUY BOUSFIELD, M.B., B.S., Medical Officer, Diphtheria Immunisation Clinics of Metropolitan Boroughs of Camberwell and Lambeth.

5s., postage 3d.

PRINCIPLES OF PRACTICAL BACTERIOLOGY FOR SCIENTIFIC WORKERS

By J. H. JOHNSTON, M.Sc., and R. H. SIMPSON, M.D.

SECOND EDITION. Over 1,350 Illustrations. 21s., postage 9d.

A TEXT-BOOK OF BOTANY for Medical & Pharmaceutical Students

By JAMES SMALL, D.Sc., Ph.C., F.L.S., Professor of Botany, Queen's University, Belfast.

By Prof. R. T. HEWLETT
King's College, London.

BACTERIOLOGY

Eighth Edition. 33 Plates, 63 Text-figs. 18s., post. 9d.

PATHOLOGY General and Special

Fifth Edition. 48 Plates, 12 Text-figures. 18s., post. 9d.

PREVENTIVE MEDICINE

12 Charts, 5 diagrams. 18s., postage 9d.

THIRD EDITION. 200 Illustrations. 21s., postage 9d.

Revised and Enlarged by 25 Eminent Contributors.

MICROBIOLOGY

A Text-book of Micro-Organisms, General and Applied.

Edited by C. E. MARSHALL, Professor of Microbiology, Massachusetts Agricultural College.

SECOND EDITION. 167 Illustrations. 21s., postage 9d.

MENNELL'S MASSAGE: Its Principles and Practice

"The book appears to us to be the best on the subject for the use of medical men."—BRITISH MEDICAL JOURNAL.

London: 40, Gloucester Place, Portman Square, W.1

ANGLO-FRENCH MEDICAL LIBRARY

Edited by F. G. CROOKSHANK, M.D., F.R.C.P.,
and Professor RENE CRUCHET

First Three Volumes

DISEASE AND THE MAN

By GEORGE DRAPER, M.D. With 43 illustrations, 12s. 6d. net

"He urges the physician to study, not only disease but man, that he may be able to view the patient's personality from every angle. The present work sums up his conclusions respecting co-relations between morphological, physiological, immunological, and psychological characters. A well-arranged text, supplemented by admirable illustrations, makes the work pleasant to read."—*Times Literary Supplement.*

EPIDEMIOLOGY OLD AND NEW

By Sir WM. HAMER, M.D., F.R.C.P. 9s. net

"An important contribution to the study of epidemiology. Should be read by all who practise the science and art of medicine."—*Medical Officer.*

ASPECTS OF AGE, LIFE, AND DISEASE

By Sir HUMPHRY ROLLESTON, Bt., M.D., LL.D. 10s. 6d. net

"Betrays a capacity to make out of varied details a pleasing, instructive, and inspiring story. The universal attitude will be one of congratulation."—*British Medical Journal.*

KEGAN PAUL BROADWAY HOUSE, 68-74, CARTER LANE, LONDON, E.C.

JUST PUBLISHED. NEW EDITION. FULLY REVISED AND ENLARGED.

SECOND EDITION. Large 8vo. 280 pp. With 306 Original Illustrations, some of which are in colour. 21s. net. Post. 6d.

DEMONSTRATIONS OF PHYSICAL SIGNS IN CLINICAL SURGERY

By HAMILTON BAILEY, F.R.C.S.Eng., *Surgeon, Dudley Road Hospital, Birmingham.*

The Illustrations form the prominent feature of this volume, and much care has been taken to reproduce them as accurately as possible. They have been still further improved and increased in number for this edition.

Lancet.—"It is time that a book of this nature was available in English. . . . . The author is to be congratulated upon the success with which he has carried out his task. A feature of the book is the abundance of illustrations, all of which, in addition to the excellence of reproduction, are informative."

Brit. Jour. Surg.—"An admirable book which we can recommend to all students."

Edin. Med. Jour.—"*We have nothing but praise for this book*, which should be in the hands of every student entering upon his surgical course."

ENTIRELY NEW WORK. NOW READY.

ANÆSTHESIA AND ANÆSTHETICS

By F. S. ROOD, M.B., B.S.Dunelm., and H. N. WEBBER, M.A., B.Chir.Cantab., Anæsthetists to University College Hospital, London.

The whole subject of Anæsthesia in its various forms is here considered, together with the properties and comparative merits of the anæsthetic agents in use, and the circumstances in which preliminary medication is desirable.

Among the most valuable chapters are one on Emergencies and Complications, and another on Cases of Special Difficulty.

Demy 8vo. 304 pages. With 4 Half-tone Plates, and 56 Illustrations in the Text. 14s. net.

NINTH EDITION.

CLINICAL METHODS

By ROBERT HUTCHISON, M.D.Edin., F.R.C.P.Lond., and DONALD HUNTER, M.D., F.R.C.P.Lond.

This Manual, now in its 87th thousand, has been thoroughly revised by Dr. Hutchison, with the collaboration of Dr. Donald Hunter, whose name replaces that of the late Dr. Rainy on the title-page. Help has also been given in special sections by recognized authorities on the subjects.

"Long experience in teaching has ensured a perennial demand for this handy volume."
—BRITISH MEDICAL JOURNAL.

"This new edition possesses the same clear exposition and the same wealth of detail as its predecessors."
—LANCET.

Foolscap 8vo, 698 pages. With 18 Colour and 2 Half-tone Plates, and 152 Figures in the Text. 12s. 6d. net.

For Hospitals, Institutions, and on Shipboard. . . . .

The
"METALIX-PORTABLE"
TROLLEY MODEL

THIS model is specially designed for use in hospitals, institutions, and on board ship. The trolley is mounted on rubber-tyred wheels and can be manipulated in confined spaces with the utmost ease.

In addition to carrying the apparatus itself, space is provided for all the necessary accessories - cassettes, etc.

Doctors throughout the world testify to the merits of the "Metalix-Portable." Have you given it your consideration?

AS an adjunct to the existing X-ray installation, the "Metalix-Portable" is invaluable—in Cottage Hospitals not already provided with an X-ray plant it is indispensable.

For the radiography of patients to whom a move would be undesirable or even dangerous. Use it too, in the X-ray room for all bone work requiring fine detail.

With the "Metalix-Portable" you can make radiographs of excellent definition. It is simple in use and there is nothing to get out of order.

There must be times when you feel the need for such an apparatus. Why not take the first step?—Write for full particulars now.

Intestinal Disinfection

MUCOUS AND OTHER FORMS OF COLITIS

CONDITIONS of Colitis occur at all ages, and lead to much suffering, ill-health and chronic invalidism. They are caused by a great variety of bacteria, which, owing to a loss of resistance on the part of the mucous membrane of the colon, maintain a chronic infection, with inflammation of this portion of the intestinal tract.

Vaccine therapy is frequently tried in this condition with disappointing results, as it is pure chance if the causative organism is isolated from the host of bacteria present.

The rational treatment is obviously to administer an efficient germicide which will attack and destroy *all* the bacteria present. Kerol is the one substance which possesses this power, and its administration has cured many a case of mucous colitis.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

REGETHERM POULTICE

(Cataplasma Kaolini. B.P.C.)

CLEAN & CONVENIENT IN USE

More certain in its action than the old-fashioned poultice.

The healing action of Regetherm Antiphlogistic Poultice is governed by its ability to prolong and maintain an even degree of heat over a lengthy period. Moreover, the ingredients are so balanced that this action does not set up any counter-irritation, but allays pain, ensures an even circulation through the congested areas, and thus induces natural and pain-free rest.

The Medical Profession will appreciate the fact that the action of Regetherm Poultice is much superior to that of fomentations or linseed poultices, and can be relied upon as an efficient aid in the treatment of all types of inflammation—whether local and superficial, or of deep-seated origin.

PRICE 2/- PER 1-lb. TIN

(NOTE THE WEIGHT).

Full size trial sample free to any medical practitioner, in British Isles, on application by postcard to Boots the Chemists, Station St., Nottingham.

Food Poisoning—
The Kaylene Treatment

The following letter has been received recently.

MESSRS. KAYLENE, LTD.

DEAR SIRS,

I am in receipt of your sample of Kaylene, for which I thank you. I do not dispense and do not wish to be without some in the house.

My last sample was used on a patient suffering from acute Ptomaine poisoning following a meal of shell fish (mussel) at 10.30 p.m. Symptoms first appeared at 12.30 a.m., and when I saw him at 3.0 a.m. he was vomiting blood and passing almost pure blood per rectum. He had commenced cramps and nervous twitchings which would shortly have gone on to tonic convulsions. He was very collapsed and had a weak pulse. I gave him only Kaylene in cold water, one drachm every quarter of an hour, from 3.0 until 8.0 a.m., when I felt it safe to leave him. For the next two days Kaylene was given every one to two hours, and was then followed by Kaylene-ol. No other medication of any sort was used, and he made an excellent recovery. This follows a somewhat similar case which I treated at the end of last year.

Your excellent preparation should supplant Bismuth for any purpose.

Yours faithfully,

Physician to ———. ———, M.B.

Manufactured by American Apothecaries Co., New York.

BY APPOINTMENT

FIRST ADOPTED BY THE MEDICAL PROFESSION A HUNDRED YEARS AGO—

TODAY OUT OF EVERY 100 DOCTORS INTERVIEWED 99 RECOMMEND IT

NEARLY a century ago, Mr. Brand—famous for his skill in perfecting fine foods—first made Brand's Essences.

In collaboration with a prominent doctor, he developed an exclusive process whereby the Essences of meats could be conserved in their natural form.

From that time until now, Brand's Essences have been recommended by the Medical profession as an invaluable aid in serious illness, exhaustion, and during convalescence.

For, by stimulating the gastric juices, Brand's Essences promote the appetite and restore vitality without strain on the digestive organs.

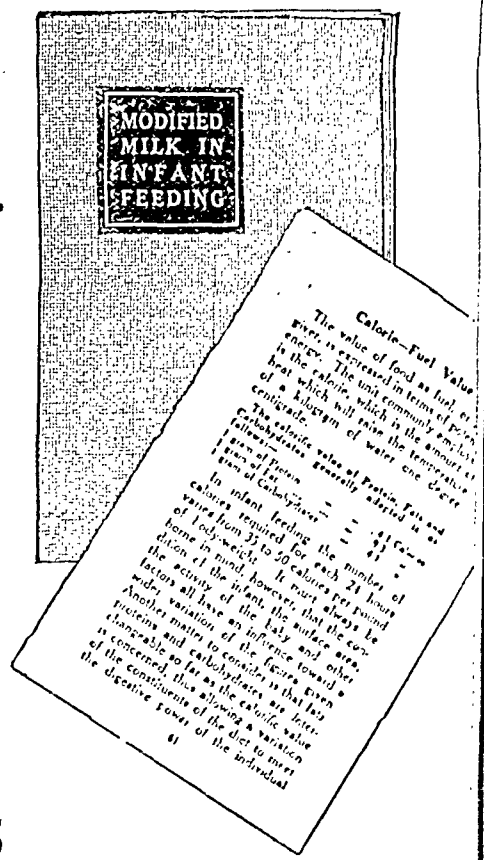
Brand's Essences consist entirely of the pure juices of freshly killed British meats in their natural combination. They are prepared by a hygienic process and sterilized under scientific supervision. No gelatine, colouring matter or preservatives are added.

Brand's Essences (Beef, Chicken, Mutton) can be obtained throughout the world at chemists and stores in small and large-sized tins and glasses. Brand & Co. Ltd., Mayfair Works, South Lambeth Road, London, s.w.8.

BRAND'S ESSENCES
(BEEF, CHICKEN, MUTTON)

A free sample will be forwarded on receipt of professional card

A diet of



Mellin's Food

in conjunction with fresh cow's milk and water, produces an immediate gain in weight in fermentative dyspepsia and in the wasting disorders of early infancy.

As is well known, sugars exhibit varying tendencies to fermentation in the digestive organs—milk sugar ferments most rapidly, less rapidly cane sugar, and maltose still more slowly, and the high percentage of maltodextrin in Mellin's Food accounts for its usefulness in all such cases of malnutrition.

TO MEMBERS OF THE MEDICAL PROFESSION.

The pamphlet "Modified Milk in Infant Feeding" will be forwarded with samples post free upon application to:—

MELLIN'S FOOD Ltd., LONDON, S.E 15

ACRIFLAVINE

"B. D." Brand

The Original British Brand of Acriflavine

The Flavines are diamino-acridine compounds which possess powerful antiseptic properties; the best known of these antiseptics is probably Acriflavine "B.D." Brand—the original British product.

Acriflavine "B.D." Brand was first employed as a wound dressing, but is now used in the treatment of a number of septic conditions such as gonorrhœa, eczema, pyorrhœa, etc. It possesses one distinct advantage over other antiseptics in that its action is actually enhanced in the presence of serum.

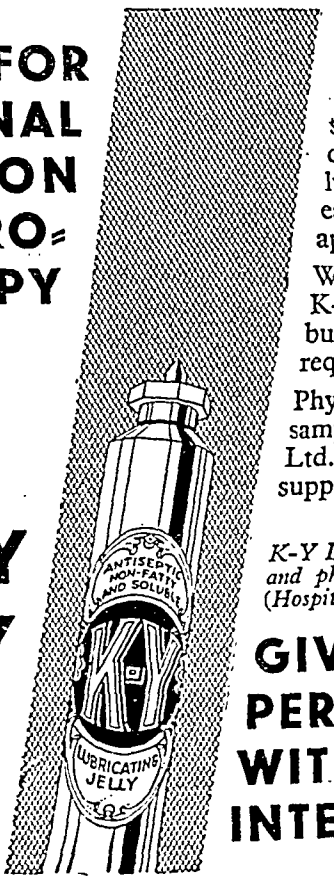
Invaluable as a Galactagogue

This nourishing and sustaining food drink is helpful to nursing or expectant mothers

NOT only hundreds, but literally thousands of cases are recorded in which this well-known preparation — Horlick's Malted Milk — has proved its efficiency as a body-building food.

It is particularly valuable as an addition to the diet of the expectant and nursing mother. For Horlick's is a perfectly balanced food containing fat, proteins and soluble carbohydrates combined together in correct nutritive ratio. It is prepared from fresh, full-cream cows' milk, selected wheat and malted barley — and, during manufacture, is partially predigested to ensure easy assimilation.

Horlick's is rich in valuable malt-sugars, but contains neither cane sugar nor free starch. It is therefore extremely easily digested, and highly productive of energy.



These characteristics make it valuable as a galactagogue. Its abundant nutriment supplements any deficiencies in the mother's regular diet, and promotes a regular and nourishing supply of milk, and its easy digestibility makes it acceptable when other forms of nourishment are unwelcome.

Taken during pregnancy, it builds up the mother and helps to maintain her vitality. A cupful taken regularly first thing in the morning frequently abolishes and almost invariably alleviates the discomfort of morning sickness.

Horlick's is now obtainable in two forms — the original, natural-flavoured Malted Milk, and the new Chocolate Flavoured form — identical in its constituents with the original Horlick's, but flavoured with fine chocolate. Horlick's is sold in sealed glass bottles, price 2/-, 3/6, 8/6, 15/-. Also in tablet form.

Further details may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

FOR INTERNAL EXAMINATION AND ELECTRO-THERAPY

K-Y JELLY

K-Y Jelly lubricates cystoscope, proctoscope, sound, bougie, catheter, rectal tube, speculum, douche tip, etc., more efficiently than any similar lubricant. It is more "slippery," flows more easily and does not bind or interfere with the application of local remedies.

When used to lubricate glass and metal electrodes, K-Y Jelly does not interfere with the current. For burns, chafing, and whenever protection of the skin is required, it is an excellent and convenient emollient.

Physicians and surgeons are invited to write for samples to *Dept. B*, Johnson & Johnson (Gt. Britain) Ltd., Slough, Bucks, stating the name of their local supply house.

* * *

K-Y Lubricating Jelly is obtainable from medical supply houses and pharmacists throughout the world. Tubes in cartons, 1/3 (Hospital size, 2/6).

GIVES PERFECT LUBRICATION WITHOUT INTERFERENCE

JOHNSON & JOHNSON (GT. BRITAIN) LIMITED, SLOUGH AND LONDON

Sanatogen Strengthens but does not Irritate

The value of Sanatogen as a tonic food lies in its ready absorption. Even the weakest stomach can easily digest Sanatogen. For this reason Prof. Ewald of Berlin University, amongst others, has frequently given it in typhoid fever and reports that it is promptly absorbed during the febrile period with apparently the same ease as under normal conditions.

Writing in "*The Medical Press and Circular*," a leading authority says:

"*Sanatogen is readily absorbed by the stomach and has an immediate and remarkable effect, shown by a steady increase of body-weight and of muscular strength and energy.*"

A New Stride Forward in Nose and Throat Therapy

Mistol is a combination of eucalyptol, menthol and camphor in a specially prepared base of petrolatum. It is approved by leading nose and throat specialists for its quick action in relieving irritated and infected mucous membranes.

Due to its oily consistency, Mistol clings tenaciously to mucous membranes, keeping its soothing and astringent ingredients in direct contact with the inflamed parts for a considerable length of time.

Mistol

Made by Nujol Laboratories.

ALOCOL

Colloidal Hydroxide of Aluminium

THE increasing prevalence of gastric ulcer and hyperchlorhydria has produced an advance in the treatment of these diseases.

"Alocol" (Colloidal Hydroxide of Aluminium) provides an antacid medicament far superior to subnitrate of bismuth, bicarbonate of soda and other alkalis. These merely afford a certain degree of ease, without bringing about a permanent relief of the condition.

"Alocol" absorbs the excess of hydrochloric acid without interfering with the normal antiputrefactive function of the gastric juice or harmfully affecting the processes of nutrition.

"Alocol" has been subject to extensive clinical trial, and literature giving full particulars of the results will be gladly sent to medical men on request.

A safe and simple antacid which is also a gentle laxative must necessarily be of great value to medical practitioners when administering to ladies and children and all who are constitutionally delicate.
May we, therefore, venture to remind you of

DINNEFORD'S PURE FLUID MAGNESIA

which has been extensively prescribed and used by the Medical Profession for a Century, and is still the best and safest means of administering Magnesia.

When prescribed for the nursery, too, Dinneford's Magnesia has always proved immensely useful as a corrective, and when mixed with infant's food it prevents many of the troubles which are due to acidity, flatulence, etc.

We are confident that you will find in Dinneford's Fluid Magnesia a reliable and safe solution which may be freely used for many ailments, and we would request your kind consideration of its use as occasion offers.

Dinneford's Pure Fluid Magnesia possesses antacid and laxative qualities which are incomparably better than those of any of the various preparations of Magnesia, in powder, now being introduced.
It cannot harm the most delicate constitution and is at all times a safe and effective laxative.
Manufactured in London for the past 100 years.

DINNEFORD & Co. LTD.

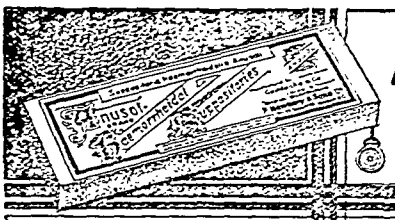
London Distributors: JOHN BELL & CROYDEN, 50-52, Wigmore Street, W.1.

The Medical Profession when prescribing "Liquor Carbonis Detergens" SHOULD ADD THE WORD



Wright's

On receipt of your professional card, a package will be sent containing a sample of each of the following—

Wright's Coal Tar Soap.
Wright's Coal Tar Ointment.
Wright's Lysol.
Wright's Liquor Carbonis Detergens.

Although there is no secrecy as to the composition of Liquor Carbonis Detergens (it is described as "an alcoholic solution of coal tar"), the method of manufacture is unique. Imitations will be found to be produced by simple digestion, usually accompanied by some primitive, perfunctory, and inadequate stirring; whereas, in the case of the genuine product, the intimate contact required, for the complete extraction of all the soluble antiseptic constitutents, is attained by a series of complicated processes, involving the use of highly specialized machinery.

WRIGHT, LAYMAN & UMNEY LTD., 66, Park Street, Southwark, S.E.1

Removing one burden of pregnancy

Haemorrhoids not infrequently add to the discomforts of pregnancy. Whether caused by pressure from the gravid uterus, or previously existent, they are aggravated by this condition.

Anusol BRAND Haemorrhoidal Suppositories

afford prompt relief from the pain, they allay the inflammation and control haemorrhage.

In pregnancy, indeed, Anusol Brand Suppositories find their most important field of usefulness.

A trial of Anusol Brand Suppositories will prove a satisfying experience. May we send you a liberal trial package?

a new antiseptic

QUINANIL

ANIL - QUINOLINE 48 S

THIS important new antiseptic is the result of Research carried out by a group of workers at the University of Leeds under the auspices of the Medical Research Council. It has been subjected to thorough clinical trials in the General Infirmary, Leeds.

Boots Pure Drug Co. Ltd. have been supplying QUINANIL for these clinical trials, and the results were reported in the LANCET of November 9th, 1929.

Every batch of QUINANIL-BOOTS is submitted to the University of Leeds for approval before issue, and ample supplies are now available for the use of the Medical Profession.

QUINANIL is usually employed in solution in normal saline. The strengths used have varied from 0.005% (1 : 20,000) to 0.1% (1 : 1,000). See LANCET of November 9th, 1929, p. 969.

5 Important points of Cow & Gate Chocolate Milk

"The Ideal Medium for Prescribing Milk"

PURITY

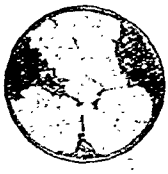
COW & GATE CHOCOLATE MILK is a blend of specially chosen chocolate, full cream milk and sugar. The milk is obtained from the rich West of England pastures. It is dried and blended with the other ingredients by a special Cow & Gate process, which preserves the vitamins and at the same time yields bacteriological sterility. IT IS THE ONLY FOOD OF ITS KIND WHICH DOES NOT REQUIRE THE ADDITION OF MILK.

PALATABILITY

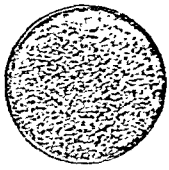
COW & GATE CHOCOLATE MILK is an excellent vehicle for the fat ration required by those people who refuse fat in the ordinary forms. It will appeal to the most fastidious taste.

DIGESTIBILITY

COW & GATE CHOCOLATE MILK contains negligible amounts of tannin and does not upset the digestion in the same manner as tea and coffee. Further, the curds of COW & GATE CHOCOLATE MILK are much finer than those of ordinary cocoa and milk. (See illustrations.)



SEDATIVE PROPERTIES

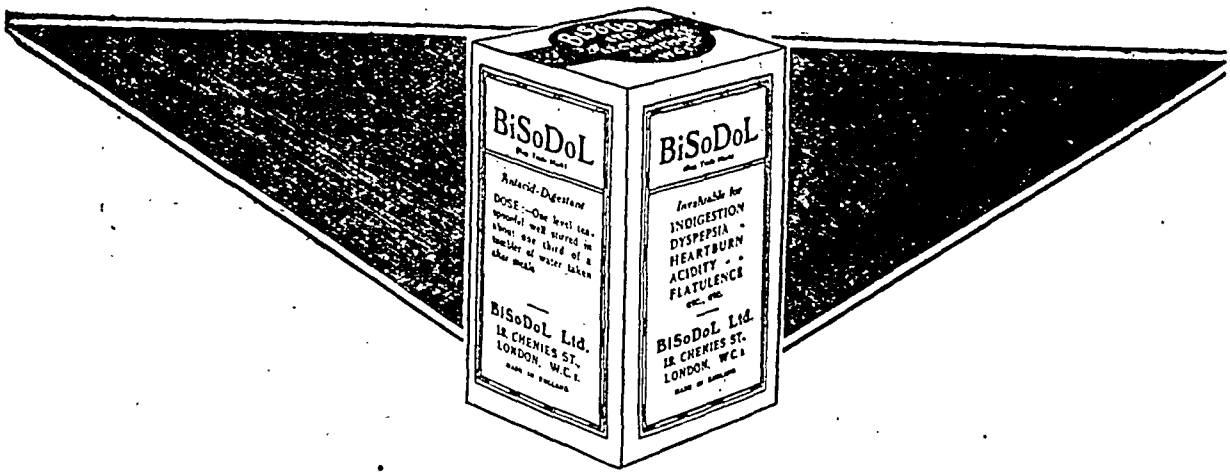


COW & GATE CHOCOLATE MILK contains very little caffeine or theobromine, and has proved extremely beneficial in cases of insomnia.

INDICATIONS

COW & GATE CHOCOLATE MILK is specially valuable to the growing child, who can thus be coaxed without difficulty to take extra milk in a palatable way. To the worker; to the expectant and nursing mother; to the aged and infirm, it presents a delicious and nutritious tonic beverage.

COCOA MADE WITH COWS' MILK



COW & GATE CHOCOLATE MILK

The makers will gladly supply samples for clinical test and any further information required, and wish to remind Members of the Medical and Nursing Professions that the Cow & Gate Laboratories are always at their disposal for experimental work in connection with Milk Foods, and that they will be delighted to arrange visits to their factories in the West of England at any time.

The Alkalies in Respiratory Diseases

Recent work on influenza, the common cold, pneumonia, and catarrhal fevers in general, has served to focus attention on the value of the alkalies in the treatment of these infections. It has been found that a system saturated with alkalies increases the resistance to bacteria. During the influenza epidemic of 1918, patients so alkalinised showed a low mortality rate and, in the main, a quick convalescence.

BiSoDoL, a balanced alkalinising agent, may be effectively employed to combat acidosis and build up the alkali reserve without upsetting the stomach or causing alkalosis.

The utility of BiSoDol as an antacid in hyperchlorhydria, gastritis, gastric and duodenal ulcer, has been abundantly demonstrated. It has also been given with marked success for the control of cyclic vomiting and the morning sickness of pregnancy.

BiSoDoL

Samples will be gladly sent to Physicians on request.

A well-known Children's Convalescent Home recently conducted a series of tests to determine the effect of Bemax on debilitated children.

The appended chart shows the increases of weight recorded during the test period, when suitable quantities of Bemax were added to the ordinary dietary. The Medical Officer of the Home records that the general improvement in health and stamina was in many cases remarkable, absence of the usual colds and other winter ailments being an especially notable result of the treatment.

Bemax is a tonic cereal food containing a higher percentage of natural Vitamin B than any known substance, as well as Vitamins A and E, and valuable mineral salts.

Bemax restores to the diet those essential vitamins that modern food lacks, and so re-establishes healthy digestion, correct elimination, and complete bodily well-being in all cases of ill health resulting from vitamin deficiency.

Bemax should be considered an indispensable part of the regular dietary of every growing child and adult.

WHOOPING COUGH

Whooping Cough is a condition in which treatment with a suitable vaccine has proved remarkably successful. Some Practitioners, however, are deterred from using Vaccines, owing to fear of reactions, but this objection may be overcome by employing Detoxicated Whooping Cough Vaccine (Genatosan). In the preparation of this vaccine all the toxic elements of the germ are removed; as a result it is given to young children and infants without any harmful reaction and produces a high degree of immunity.

The following extract from a Practitioner's letter may prove of interest:—

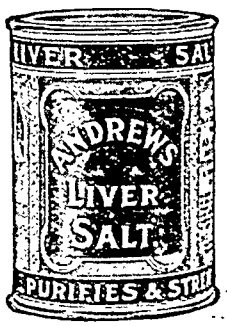
"..... Some time ago, I resolved to try for the first time a vaccine in whooping cough and the results were so excellent, that I thought you would be interested to hear from me.

(*a*) Three children aged 3 years, 2 years and 8 months, were treated when the disease was about 10 days established; all were completely cured after the third injection—the mother described the effect to me as simply miraculous.

(*b*) Two aged 6 years and 3¼ years, who had relapses, were well after they had got the 2nd injection.

(*c*) An infant aged 8 months—the whoop disappeared after 1st injection. The cough was gone after 2nd injection, and the mother, who had tried everything and despaired of the child's life, was exceedingly grateful and assured me it was simply wonderful to see how the child had slept for the first time for days and was able to retain its food and rapidly put on weight. The Vaccine used was your Detoxicated Whooping Cough Vaccine. Speaking for myself, I can only describe the effects as magical, as the children were worn out and emaciated from coughing, vomiting, and loss of sleep."

Additional information regarding the above Vaccine will gladly be supplied to any Practitioner who writes to The Vaccine Department, Genatosan Ltd., Loughborough, Leicestershire.



Constipation

In spite of dietetic measures and exercise many patients still suffer from the devitalising effects consequent upon intestinal stasis. To such, the attainment of perfect health is debarred. Whether in disease or convalescence faecal stagnation retards recovery.

In health and in the majority of pathological conditions, an efficient and safe aperient will be found in Andrews Liver Salt. It is a briskly effervescent Saline with a pleasant taste.

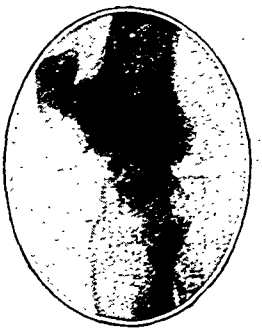
Antacid in action, it stimulates the secretion of bile and of the mucus glands of the intestines, and causes a semi-fluid stool and a painless, easy evacuation.

Especially indicated in the constipation of childhood and old age; of inestimable value to those who travel; and a valuable adjunct in the treatment of those conditions incident to hepatic congestion and torpidity.

Dose ½ - 3 teaspoonfuls (according to requirements) in a glass of water.

An 8-oz. Tin sent free on request.

Andrews Liver Salt



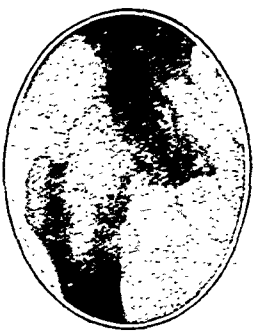
SCOTT & TURNER LIMITED, Works and Laboratories at Newcastle-on-Tyne

'IODOLYSIN'

Trade Mark.

A Powerful Fibrolytic Agent

Strikingly Successful in Chronic Arthropathies



Radiograph of Knee-joint in Rheumatoid Arthritis

A fibrolytic agent which gives really satisfactory results in a large percentage of cases must appeal to the general practitioner who has constantly to deal with difficult and intractable cases of chronic rheumatism and allied conditions. This can be justly claimed for 'Iodolysin' which has a striking effect in Rheumatoid Arthritis; and it is also employed with advantage for the removal of all forms of pathological fibrous tissue.

'Iodolysin' is a chemical combination of Iodine and Thiosinamin with these special advantages:

Ready Solubility in water. Well tolerated. Absence of local reaction on injection

'Iodolysin' is supplied in ampoules for hypodermic injection; in capsules for oral administration, or as an ointment or paint for local application.

Radiograph of Hip-joint in Rheumatoid Arthritis

Arris and Gale Lecture

ON

ANATOMY, ORTHODOX AND HETERODOX, IN RELATION TO SURGERY.

DELIVERED BEFORE THE ROYAL COLLEGE OF SURGEONS OF ENGLAND ON FEBRUARY 19TH

BY

W. McADAM ECCLES, M.S., F.R.C.S.,
CONSULTING SURGEON, ST. BARTHOLOMEW'S HOSPITAL.

WHAT was orthodox in 1646 when Edward Arris founded the lectureship was that the holder of the office, which I have the *honour to-day to possess*, should be a "Reader of the Muscular Lecture." I leave it to you to judge exactly what was meant by this title, for by it I shall undoubtedly be heterodox now. My later predecessors in office were styled "Masters in Anatomy," and included Percivall Pott and John Hunter.

John Gale founded the Gale Lectures in 1655, nine years after the foundation of Arris, but the earliest recorded lecture under this trust was in 1698, when Dr. Havers, of Haversian canal fame, was appointed to deliver "an Anatomy Lecture called Gale's Anatomy." Subsequently it was styled "The Osteology Lecture." Thus we have these two ancient foundations concerned with muscles and bones, and I am not so very sure that we have got away *from the trammels of osteology and musculature even* in the present, when the student starts learning facts concerning these, and spends perhaps far too much time thereon. In 1810 the foundations were united, and in 1857 the title of the lecturer was changed to that of Professor of Human Anatomy and Surgery. In 1864 it was enjoined that there be three lectures each year, and upon human anatomy and physiology, but it was with the desire to revert to the older title that I have chosen the subject of my lecture to-day. Our President, Lord Moynihan, held the lectureship in 1899 and 1900, and possibly he may remember how he thrilled his audience by his dissertation on retroperitoneal hernia, and the rarer forms of hernia, a subject which I had, and still have, very much at heart.

Now what is orthodox and what is heterodox in anatomy? Orthodoxy we must take to mean merely the holding of right or correct opinions—that is, such opinions as are currently accepted as correct. We have to remember that the stake has claimed some who held similar opinions. Heterodoxy is presumably the opposite—that is, holding opinions not in accord with established doctrine or practice.

Orthodoxy in anatomy may be described as the orthodoxy of the textbook, the teacher, the teaching, and the examination, both anatomical and surgical. Many a student has said to me that if a statement is found in a textbook it must be correct. But it is the wise man who doubts even infallibility, though he must be prepared possibly even to suffer for his rashness.

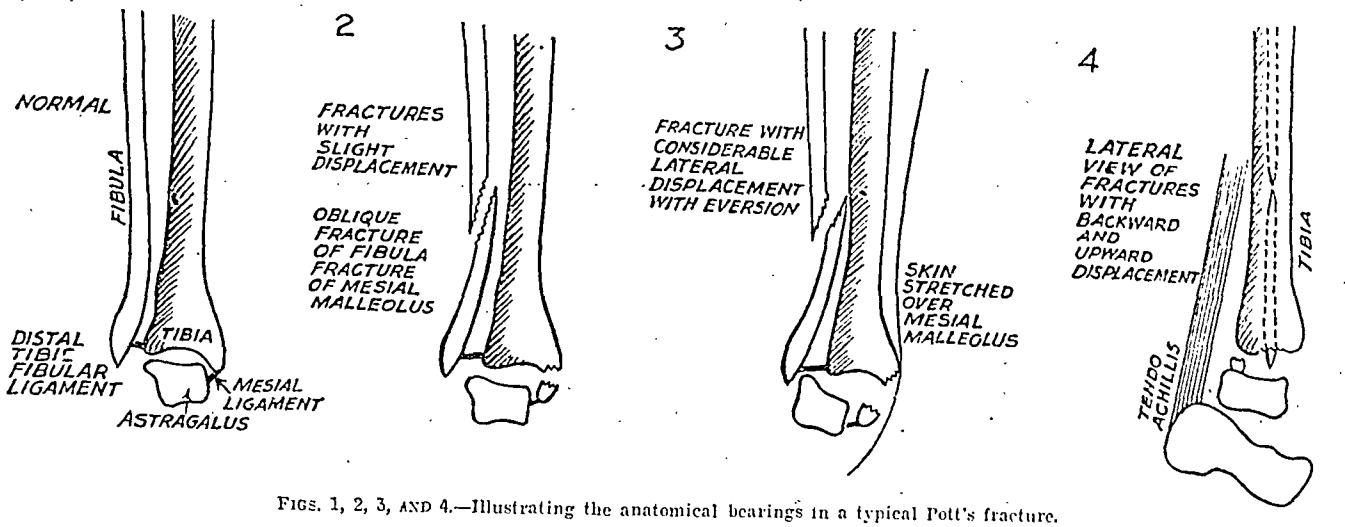
A statement, further, may be right, but it may be so interpreted by the reader as to be wholly wrong. You know the tale of the candidate in an examination in chemistry who astonished his examiner by asserting in his written reply to a question concerning hydrogen that this gas "was not found in Ireland." In the viva voce he was taken to task concerning his statement, but persisted that he was right, and that it would be found in his examiner's book on chemistry. The volume was procured, and on the appropriate page there appeared these words: "Hydrogen is seldom if ever found in the free state." To such—may I call them parasitic students?—I have generally ventured to say that with greater experience they would find that modification of exact statements *even in textbooks is good for the soul, although it* might lead to a shaking of faith in so-called "orthodoxy." Many a younger teacher has confessed to me that he was in the trammels of the textbook orthodoxy, and dare not attempt to escape therefrom when instructing those under his tuition. This is deplorable. Better be bold than cowardly, better break the bands of tradition than continue to stereotype what is not true to fact.

The teaching of anatomy, it is often said, must be along orthodox lines because the syllabus and the examiners force it to be so. It is true that the overpressure of examinations is too great, but it is almost inevitable. Sir Michael Sadler, when commenting recently upon this subject, said that examinations acted as a "cold shadow on education," and that students thereby "learn things on paper instead of going direct to the facts themselves." What a sidelight this is on the student reading anatomy in the library rather than dissecting in the rooms or feasting his eyes *upon the beautiful anatomical preparations of our College* museum!

Heterodoxy in anatomy implies, it would seem, a disbelief in much of the old tradition and teaching, in conforming less and less to the preconceived ideas of our forefathers when facts force us so to do. Careful observation is the father of correctness in description, and familiarity with form tends to improve comparison.

ERRORS OF OBSERVATION AND DESCRIPTION.

Anatomy has been built solely on the results of observation; imagination works havoc if it is allowed to enter this domain. But some very obvious errors—obvious to us—have been perpetuated as the result of observation on the cadaver. An extraordinary example of this is the term "artery," an air-conveying tube. Nothing is farther from the truth, but it would perhaps be sheer pedantry to attempt to change the name of this type of vessel after so long a usage. It is probably on account of this error that even the modern novelist attributes much more importance to the "veins" than to the "arteries" of the "subject" with which he is dealing.



There are, however, many other glaring instances of looseness in nomenclature and of description, which should have been based on careful observation, and should be changed even to-day. I will mention but a few of these to show what I mean thereby.

Submaxillary lymphatic glands. This is wrong. There are two maxillae and there are lymphatic nodes—not glands—and these are not directly below either of them, but they are beneath the mandible. Therefore, these lymphatic nodes should be styled submandibular lymph nodes.

Deep cervical fascia. I venture to assert that no surgeon, however many times he may have undertaken dissection in the neck of a living person, has ever seen this structure. The elaborate description given in most textbooks on anatomy serves only to bewilder the student and is of no use to the surgeon.

Pott's fracture, which should be termed the lateral fracture dislocation at the ankle-joint, is usually stated in the surgical textbooks to be a fracture of the fibula with tearing of the internal lateral ligament of the ankle or separation of the internal malleolus, and displacement of the foot outwards, and this, regardless of how the anatomical factors insistently influence the production of the lesion and the displacement of the foot. Reviewed from an anatomical point of view, this fracture-dislocation should be described thus: The strain of the body weight being suddenly brought to bear upon the mesial ligament of the ankle-joint, the mesial malleolus is dragged off at its base, the bone being more brittle than the elastic ligamentous tissue. The force now acts through the astragalus on to the lateral malleolus, but the fibula is held firmly to the tibia by the distal tibio-fibular ligament. Hence the strain is in reality on the fibula at a spot which is proximal to the ligament, and the fibula gives way, with the line of the fracture from above downwards and laterally. Then displacement of the foot occurs immediately, and in a direction which is lateral, with eversion, and backwards and upwards by the pull of the strong

gastrocnemius and soleus muscles through their calcaneum tendon. (See Figs. 1, 2, 3, and 4.) The description, I grant, is "heterodox" when viewed from the traditional textbook read by the student, but it is really "orthodox" when viewed in the light of anatomy. I leave you to judge which is the better.

FIGS. 1, 2, 3, AND 4.—Illustrating the anatomical bearings in a typical Pott's fracture.

The Anatomy of Inguinal Hernia.

I have paid particular attention to this subject, and especially in the living person, and I am convinced that a large portion of the orthodox description of the parts as given in many of the leading textbooks of to-day, both of anatomy and surgery, is grossly misleading. Time will not permit me to give more than a few instances to prove my contention.

The latest edition of one of the most popular textbooks on anatomy makes the following preposterous statements: "A triangular opening, the subcutaneous inguinal ring." But how can a triangle be a circle? (See Fig. 5.)

Again, "The inguinal canal extends from the abdominal inguinal ring to the subcutaneous ring." I venture to ask each one of my listeners this afternoon, has any one of you actually seen an abdominal inguinal ring? Frankly, no such opening exists in the living subject. I am quite willing to admit that when an oblique inguinal hernia is present, the sac at its connexion with the parietal peritoneum may have a thickening upon it, which may be styled a "ring," but this is a pathological condition, and not one to be found in the normal body. There is no such opening as that which used to be called the "internal abdominal ring." Then why perpetuate its existence or quasi-existence?

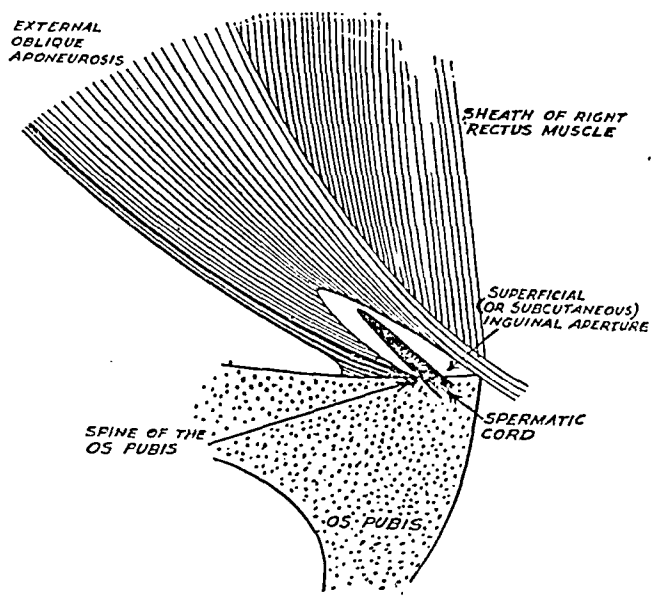


FIG. 5.—Diagram of the superficial anatomy of the inguinal region.

To crown all, we are told "the seat of stricture is either the abdominal or the subcutaneous ring; most frequently at the former situation." Extraordinary! How can strangulation be caused by the edges of a non-existent opening? But another textbook on anatomy makes a still more astounding statement: "The place of exit of an inguinal hernia is a split in the aponeurosis of the obliquus externus." And yet a patient may die of the results of strangulation of an inguinal hernia which lies completely within the inguinal canal!

Lastly, here is a quotation from a Continental anatomical work. "The annulus inguinalis subcutaneus . . . is formed by the separation of the lowest fibres of the tendon of the m. obliquus externus . . . giving rise to an acute angled space." Obviously, this is intended to convey the idea that the superficial inguinal aperture is a triangle, and not an annulus.

Turning to the most recent textbook on surgery, still worse nomenclature is perpetuated. The expression "internal abdominal ring" cannot be maintained on any grounds, even if such an aperture existed, for it is not "internal" but "deep," it is not "abdominal" but "inguinal," and it is not a "ring" but an "aperture"; but above all it does not actually exist, except perhaps as an abnormality. Now this from the same book: "It is always possible to invaginate the skin of the scrotum and insert the finger into the hernial aperture, to explore its extent and relations, and to detect any impulse." No wonder an action was brought once against a medical practitioner who performed this manœuvre, his patient alleging that his doctor had actually caused his "rupture"!

I have recently seen instructions issued eighty-five years ago for determining the physical fitness of candidates for the City of London police force. Among the more common causes of rejection is mentioned "Hernia, or a tendency to that disability from preternatural enlargement of the abdominal ring." This "ring" I take to be what the examiner in those days would have called the "external abdominal ring." This aperture, of course has nothing whatever to do with the incidence of an oblique inguinal hernia, and not often greatly to do with its progress. I much fear that examination has not advanced greatly since that day in 1844, for I recently heard several well-known surgeons still teaching this nomenclature, when, of course, the right term is "superficial inguinal aperture."

THE TEACHING OF ANATOMY.

I have been, perhaps, too insistent on this one area of the inguinal region, but it is only one example of many which I could quote to prove my contention of the need of more "heterodox" anatomy. I now turn to what I may call "heterodoxy in the teaching of anatomy."

I was impressed as a teacher myself, and perhaps still more as an examiner in this subject, with the cramping character of the "isolated" anatomy taught and its effect upon the examinee. By "isolated" I mean anatomy unconnected with the future professional work of the student when he becomes a general medical practitioner, and not

only in the "surgery" of the same, but almost equally in the "medicine" of this class of practice.

I am still of much the same opinion, although a quarter of a century has passed since those days. But in order that I might be really up to date in information on this matter, I wrote to a large number of the present-day professors of and lecturers on anatomy, putting before them two questions:

1. Are you satisfied that the present system of teaching anatomy to the average student conduces to a knowledge really helpful to general practice?

2. If not, what changes would you suggest?

I have been honoured by replies from twelve, and their answers have been so helpful to my subject that I shall venture to make general use of much given, and to refer in detail to some of them. Seven—more than half—are not satisfied that a really useful knowledge of anatomy is obtained by the average student. This opinion is not due to modesty in teachers who desire improvement and are uncertain that their method of teaching is the best. Their teaching has to be "orthodox," partly because the student is examined in the "orthodox" manner, and partly because the textbooks are still too "orthodox." Some give examples of this contention, and I will inflict one upon you.

Here is an "orthodox" anatomical question, which on the surface looks quite sound: "Describe the ankle-joint." While to the "book student" it should have no terrors, and the reply to the question may be all that is required by the examiner, there is but little in it to draw forth that deeper knowledge which is going to be the practitioner's standby in practice. The same question couched in heterodox terms might be: "What movements can take place at the ankle-joint? Describe how they are controlled and limited." There is "spirit" in a question put in this way, while the former is "dry" bones or little more.

The teaching, therefore, for the "orthodox" question need be no more than the stereotyped textbook description, but for a good reply to the "heterodox" question it would be necessary that the teaching should be admittedly "heterodox." To carry out such methods of teaching would necessitate the use of an *x*-ray plant for screening the joint and its movements, the employment of a living subject for the same, and the inspection of a badly set fracture-dislocation at the ankle-joint. In this manner can be demonstrated the reason why the anterior dorsal surface of the astragalus is broader than the posterior, and that lateral movement can only be obtained in plantar flexion because of the locking which occurs in full dorsiflexion. Structure and function are here depicted and closely co-ordinated, instead of the divorce so frequently found in the orthodox teaching.

In a recent examination paper in surgery every one of the questions, and perhaps rightly, had a distinct anatomical bearing. The two questions above the line, one of which had to be answered, were purely anatomical, as intended they should be, and were very orthodox at that. One referred to the prostate and the other to the pronator radii teres. The other four "surgical" questions were concerned with "cut-throat," obstructive jaundice, acute otitis media, and caries of the lower thoracic region, and not one of them could be answered well and sufficiently without a good practical understanding of the anatomy of the several regions involved. Now, did the students who sat for this examination have their anatomy brought before them in the orthodox manner, and with little reference to abnormal conditions such as those upon which they were being examined, or was their anatomy presented to them as a "living" subject fraught with all the probabilities of their actual work in practice?

If, then, anatomy looms so largely in many examination papers, for this reason alone it is desirable that the student in his later years of the curriculum be taught more anatomy from the clinical point of view than perhaps he has ever been so taught before. I was so struck with this necessity that in 1906 Dr. C. R. Box and I collaborated in writing a book on "Clinical Applied Anatomy," to which we gave a sub-title, that of "The Anatomy of Medicine and Surgery." Nearly half a century previous to this John Hilton had produced his classical work on "Rest and Pain," and we were imbued with the idea that the right way in which to approach clinically applied anatomy was just the opposite to that in which it was usually approached.

The "orthodox" manner was to deal with the different parts of the body and to link on to the description of them some remarks as to the abnormal conditions that might appear therein. The "heterodox" view that we took was that the subject would be better reviewed by taking the various diseases, disorders, and injuries to which the human frame was liable, and show how anatomy influences their incidence and progress. In this endeavour we purposely omitted all non-essential anatomical points, and made the work a practitioner's rather than an anatomist's view of anatomy. Some may possibly regret that this work is now out of print.

It is essential that the student during his fourth and fifth years should maintain that knowledge of anatomy with which he was endowed when he entered upon his clinical studies, and it would probably be to his advantage if he even added to it. But I am convinced, and I think the opinion of most of the teachers of anatomy is the same, that much more of the "heterodox" anatomy should be available for the student prior to his entrance to the wards, if he is going to have the anatomical knowledge so needed in elucidating his cases therein. To this end I would further urge that it should be made possible for the student during the time of his dissecting the body to see typical clinical instances which illustrate common points in anatomy.

There are numerous "chronic"—that is, permanent—cases, which should be available at the time they are needed. I am thinking of such as a typical uncured ulnar nerve paralysis, which should show more forcibly than all the textbook description, and even the dissection of the nerve, its peripheral distribution, the characteristic position of the digits, and particularly that of the ring and little fingers. Then the anatomical reasons for the results can be demonstrated, and the student impressed with the fact that, after all, anatomy is of some real use.

I know that most of the teachers of anatomy would welcome a much closer connexion between their department and the clinical side. When the medical school and the hospital are adjacent, there should be no real difficulty in bringing about this co-operation, if both parties were really keen on the matter.

Why should not the anatomist be invited to the ward, there to give a short dissertation on the anatomical bearings of the case at hand? Or why should not the surgeon visit the anatomical department, and there instil into the anatomy student a desire to know anatomy because it is going to be a matter of real importance to him in the future?

CONCLUSIONS.

I would sum up what I have endeavoured to put forward in this lecture.

1. Anatomy must be freed from the trammels of "orthodoxy" if it is to be of real use in surgery, and particularly the surgery of general practice.

2. The teaching of anatomy is still far behind what it should be in reference to surgery, and the anatomical knowledge of the average general practitioner is not practical enough.

3. The teaching of so-called "clinical applied anatomy" requires to be organized in a much more definite manner, and should occupy even more time than it does when it is taught best.

4. The recriminations, still extant, of anatomist on clinician and of clinician on anatomist might all disappear, and watertight compartments obtain access to one another.

What of the future of anatomy? We need have no anxiety. Anatomy will ever be with us, and that is good. Anatomy will never change—it is the most concrete of sciences, except perhaps that of mathematics. But the facts of anatomy are not likely to diminish in number; they will grow, and probably grow enormously, as knowledge of the human body increases. Then it will be still

more impossible, if this can be, for one human brain to assimilate the whole of these facts and put them to practical use. The burning question even now is, How many of these facts is it desirable—should we say necessary—for a general practitioner to know?

What I wish to further is the teaching of anatomy in such a manner that the finite mind may obtain and retain those which are essential. I consider that this requires a good deal of "heterodoxy" in the relating of anatomy to surgery.

A British Medical Association Lecture

ON

THE DIAGNOSIS AND TREATMENT OF PULMONARY TUBERCULOSIS.*

DELIVERED BEFORE THE FIFE BRANCH, OCTOBER 31ST, 1929,

BY

W. ARNOTT DICKSON, M.D., M.R.C.P.ED., F.R.C.S.ED., D.P.H.,

TUBERCULOSIS OFFICER, GLOUCESTERSHIRE; MEDICAL SUPERINTENDENT, STANDISH HOUSE SANATORIUM; CLINICAL MEDICAL OFFICER, GLOUCESTERSHIRE COUNTY COUNCIL.

(With Special Plate.)

To attempt, in however sketchy a fashion, to cover the ground indicated by the title of this address, appears little short of ridiculous. But a bird's-eye survey, if it can be compassed, admits of some sort of perspective, and thus helps to compensate for its superficiality. It is in this hope that I shall put before you, not a synopsis of the monstrous literature which has grown up on the subject, but a brief and I hope practical summary of the procedures on which I mainly rely for diagnosis and treatment in the tuberculosis department of Gloucestershire, the county to which I am attached.

That county, it may be mentioned, shows significant variations from other counties in its arrangements for carrying out the medical services statutorily imposed on it. As regards tuberculosis, there is a fusion of the offices of tuberculosis officer and sanatorium superintendent, which is, or ought to be, very valuable; and the county also possesses a treatment scheme, peculiar to itself, initiated over eight years ago through the pioneer work of the county medical officer of health (Dr. J. Middleton Martin). Under this scheme fifteen centres have been opened throughout the county staffed by the local practitioners and designed to treat the various types of cases for which a local authority has responsibility. The doctors have at call the services of the recognized consultants in the area. This scheme has recently been commended to the Council of the Association by the Gloucestershire Branch as the ideal method in a county area of securing the co-operation of private practitioners in public health services. An integral part of the scheme is that cases raising the suspicion of tuberculosis are grouped for examination at my periodical visits. As these out-stations are additional to the usual dispensary organization it will be seen that the opportunities provided for a second opinion are particularly good. My experience in the county comprises over 14,000 patients, and the sanatorium under my charge has 250 beds. For the sake of simplicity I shall, in what follows, exclude children from consideration.

DIAGNOSIS.

It is a curious fact that doctors, in the matter of diagnosing tubercle of the lung, tend to fall into two groups: those who on the strength of a suspicious symptom or so, with occasional indeterminate signs, such as a few scattered rales, are prepared almost light-heartedly to label a case tuberculous; and, on the other hand, those who wait till physical signs cry aloud for judgement. For a department like mine, needless to say, the line of least resistance is: when in doubt, diagnose tubercle. There is an ever-present danger that this diagnosis becomes simply a dumping ground. Yet a lifelong handicap may be imposed on a patient because of an ill-founded diagnosis of pulmonary tuberculosis, and however successful a sanatorium may be as a general convalescent home, that is not its function.

Of the cases sent to us year by year we give an opinion that tuberculosis is not present in between 30 and 40 per cent. It may be objected that early cases are being missed, that the golden opportunity is being allowed to escape. This, of course, is the bugbear of a tuberculosis officer's life. To that objection I reply, first, that in a large number of cases an alternative diagnosis is established. The symptoms are found to be due to diabetes, or cancer, or heart disease, or syphilis, or pernicious anaemia, or some other debilitating or wasting disease. I have also seen quite a number of young girls whose symptoms were dependent on an unsuspected pregnancy. These conditions, and many others, which like them have nothing to do with the lungs, have been found during the ordinary dispensary examinations.

In the second place, I reply that, with regard to lung cases, we have to face a formidable test of the accuracy of our negative diagnoses. Unless the patients remove from the county altogether, the fact of a subsequent notification of tuberculosis, by whomsoever made, is known to us. And should any of these patients die, and the word "tuberculosis" appear at all on the death certificate, that fact also infallibly reaches us. This furnishes a severe and continuously operating check on our accuracy or otherwise. There is, fortunately or unfortunately, nothing resembling it in ordinary general or hospital practice. From these ultimate tests we have so far emerged without finding cause to modify our standards.

But assuming that a patient is suffering from tuberculosis, we are doubtless all at one in wishing to have the diagnosis established, if possible, at an earlier stage than it commonly is at present. The need for this is admitted on every hand, though the frequent assumption that early diagnosis necessarily implies a good prognosis is not always well founded. Delayed diagnosis is not necessarily the fault of the doctor. Two weeks ago I saw at a dispensary a man who had seen his doctor for the first time only the day before. He had not lost a day's work; he said he felt well and took his food well. His only complaint was undue tiredness. Yet his temperature was 102° F., and he had active tuberculosis of most of one lung, with a large cavity. There must be few diseases which can advance to such a stage without arousing the urgent interest of the patient in his own condition. But this is rather an exceptional case. I think it must be admitted that there are other cases, even in considerable numbers, where the opportunities for examination have occurred and in which any doubt as to the diagnosis might have been resolved earlier by everyday clinical methods.

I hear very often the statement that chest cases are extremely difficult. Admittedly an obscure chest case may present as difficult a problem possibly as any met with in practice; but my point is that such cases are not nearly so common as some medical men suggest. Certainly I see many cases in which the diagnosis is *too* easy—cases which should cast no strain whatever on the clinical acumen of the examiner, but which have managed to get through the meshes of the diagnostic net.

SCHEME OF EXAMINATION.

Let me put before you, shortly, elementary though it may be, the scheme which I adopt for the investigation of a case of suspected pulmonary tuberculosis.

First the medical history is taken, and the symptoms elicited. There are some writers on tuberculosis who do not hesitate to diagnose on symptoms alone. I do not agree with them. Even haemoptysis, that most dramatic and significant of symptoms, may lead one astray. Having obtained the patient's story (and this well repays the time spent on it) he is then examined, stripped to the waist. It is surprising how often this first principle of chest examination is violated. If at all possible, the patient should

* The lecture was illustrated by numerous lantern slides.

stand facing a window. I know from experience the impossibility of making a reasonable examination of a patient in bed in a miner's cottage.

The usual routine of inspection, palpation, percussion, and auscultation is then proceeded with. It is not safe to omit any of these methods. Inspection should be conducted at some distance from the patient—six to eight feet. It is a method frequently neglected, yet in cases of extensive thickening of the pleura the limitation of movement on the affected side may be the only physical sign easily ascertained.

Palpation, apart from its customary uses, may give to the trained fingers a sensation of muscular rigidity over a lesion which is readily discernible.

Percussion, I have come to the conclusion, is a more difficult art to master than our teachers warned us. It should, in my opinion, invariably be light, very light. Apparently it requires more practice than it generally receives. In any case, the failure to detect differences in percussion note is frequent, which is unfortunate, as percussion is a more valuable guide in diagnosing early tuberculosis than is auscultation, since infiltration precedes catarrh. It is a useful rule to compare not only the apices, which may both be affected, but also the apices with the axillary region. Perhaps, in view of recent writing on the subject, it is well to make clear that the term "apex" is here used in the loose fashion usual in this country, and is not restricted to the anatomical apex above the clavicle.

The demarcation of Krönig's areas is valuable in early cases, and the use of a skin pencil has other advantages. It is an aid to concentration, it makes the examiner commit himself, and is ocular proof of a complete examination!

Auscultation is more commonly relied on than percussion, and for most examiners appears to be easier. In cases of difficulty, interrupted auscultation—that is, the comparing of each phase of respiration separately—should always be practised; and it is inspiration which demands the closest attention. The difference in breath sounds at the apices is universally recognized. It is sometimes forgotten that there is a corresponding difference at the bases, the respiratory murmur on the right side being decidedly weaker.

Some of the pitfalls in auscultation may be mentioned. An effusion may give rise to auscultatory signs almost indistinguishable from a cavity—tubular breathing in its purest form, and whispering pectoriloquy. On the other hand, a cavity may indubitably be present and give none of the classical physical signs we were taught to associate with it. There may also be great difficulty in distinguishing between pleural rales, the rales of active disease, and the rales more or less permanently present in fibrotic cases, though the distinction is important. It is not possible to lay down an easy guide to differentiation. This must be largely a matter of experience.

The examination, even up to this stage, takes one a long way. In the majority of cases of tuberculosis sent to me it settles the diagnosis. For although sputum examination may clinch the matter before physical signs are discoverable, I hardly ever see patients at that stage. And if a patient with symptoms indicative of pulmonary tuberculosis has evidence of consolidation at the upper part of a lung, the diagnosis may be made practically with certainty. Tuberculosis may have signs confined to a base, but this is so uncommon that it is a safe enough rule never to diagnose it in the absence of tubercle bacilli in the sputum.

Sputum Examination.

It is literally essential that the sputum be examined in every case; repeatedly if necessary. This is fundamental. It is a mystery why this simple test is not universally applied. Only a small proportion of the total number of patients sent to me have had their sputum examined before I see them, though many of them have had both symptoms and sputum for months. Not once, but hundreds of times, have I seen delay in diagnosis that could have been avoided by the exercise of this elementary precaution. A positive sputum, barring the extraordinarily infrequent accident, settles the diagnosis. The possibility of "carriers" is of the merest academic interest when we are discussing patients with symptoms. One negative sputum result is of little value. But three negative reports, provided the specimen is purulent, should receive great weight. It is not suggested that a progressive tuberculosis cannot be present in the absence of tubercle bacilli in the sputum. In miliary tuberculosis, as is well known, the organisms may never be found by that examination. But, personally, I make a point of overhauling the diagnosis with an open mind after three negative sputum results. In such cases a Wassermann reaction is obtained, *x*-ray examinations are repeated, special sputum tests are undertaken, and an injection of lipiodol may be given. The evidence should be strong before a chest case with definite physical signs and sputum is accepted as tuberculous in the consistent absence of the tubercle bacillus.

Pleurisy with effusion, if present, can hardly escape the examination I have described. It should always be regarded as tuberculous, and treated as such unless there is an obvious alternative explanation. I invariably put in a needle in such cases. If serous fluid is found two important points have been settled: (*a*) empyema has been excluded, and (*b*) the diagnosis has been established beyond all doubt. This is a point of some moment, for should the fluid happen to be absorbed quickly and completely, and later the need for serious treatment is questioned, it is an advantage to have one's diagnosis of effusion based on evidence which is incontrovertible. Incidentally, it is curious to note how the position of the apex beat does not always get the place of cardinal importance it deserves in suspected effusion.

To come to more general considerations in examination, it is unusual to have active tuberculosis proceeding with a normal temperature. In any case of doubt a record of the morning and evening temperature should be kept for a fortnight. The usual precautions should be observed as to the patient having been at rest for at least half an hour before the temperature is taken, and no food or drink taken for a similar period. I am assuming that the temperature is to be recorded in the mouth. In spite of all that has been written on the superiority of the rectal temperature, you may rest content with the oral method, which is very much simpler and sufficiently reliable.

The pulse frequency is often a difficulty, as many nervous patients show an abnormally high rate owing to excitement. A low pulse rate is a good sign, and it is often useful to try the effect of exercise. The old form of exercise known as "20 chair" is as good as any. The pulse frequency should return to its starting point in two minutes. A consistently high pulse rate is an unfavourable feature in prognosis.

X Rays.

No physical examination of the chest can be considered complete nowadays without an *x*-ray examination, though it is not always essential. But if nothing has been found clinically, a negative diagnosis is greatly strengthened if nothing is found by this method also, and the extent of involvement of the lungs, in a positive case, can be ascertained with enhanced accuracy from an *x*-ray film.

The reading of the film is often a difficult matter. For the majority of medical men the report of the radiologist must be taken, and this is a variable quantity. It may be said of *x*-ray examination, as of so many other things, that it is a good servant but a bad master. I have on many occasions seen films and reports on the same patient by different radiologists, and the comparisons are instructive. During the past few years I have compared many hundreds of *x*-ray films with the clinical findings. As a rule they correspond reasonably closely, but a film may be invaluable in revealing a condition inaccessible to clinical examination, and, as suggested above, this may include early cavitation. At other times a film may show nothing when signs, to auscultation at least, are obvious. This is particularly noticeable in cases of unresolved pneumonia in its later stages. As *x* rays do not reveal catarrh, you may get a film showing an apparently normal chest when one side is bubbling with rales. In primary tumour of the lung, which is said at some of the chest hospitals to be getting much commoner, the diagnosis can frequently be settled at once by *x* rays, particularly after the shadow has been

sharply delineated by the introduction of air into the pleural cavity. The condition, fortunately, does not appear to be on the increase in my county.

TESTS FOR TUBERCULOSIS.

A word must be said on the various tests for tuberculosis, of which much has been heard from time to time. Tuberculin has been used as a specific test in hundreds of thousands of cases. The von Pirquet skin test has been performed, I suppose, in every country of the world, and a voluminous literature has grown up on it. We made a thorough trial of this test at the sanatorium which I control, doing over four hundred inoculations, almost equally divided between children and adults. At first commercial tuberculin was used, and then a special brand kindly supplied for the purpose by the Wellcome Laboratories. My experience is that, using ordinary methods with presumably ordinary skill, this test is, for diagnostic purposes, of no value whatever. I go further—it is so fallacious that it may easily be worse than useless. In patients known to have tuberculosis, with tubercle bacilli in the sputum, some doing well and some doing badly, it was impossible to forecast the result, which appeared to have no relation either to the presence of active disease or to the prognosis. In known cases of tuberculosis the test was negative in almost as many cases as it was positive. This is an exceptionally bad result, but Dr. Charles McNeil, in the *British Medical Journal* of October 12th, 1929, has to admit, after a panegyric of the test, that it "may . . . fail to appear in an actually tuberculous condition." This has been shown to be the case also in guinea-pigs.

The ophthalmic tuberculin reaction is little short of barbarous, and ought never to be employed.

The intradermal reaction has been very widely used within the past few years. A study of Professor Lyle Cummins's article in the *British Medical Journal* of February 23rd, 1929, will show that this also is of no practical value in this country, however useful it may be in deciding the progress of infection in non-immunized communities.

The complement fixation test, corresponding to the Wassermann reaction in syphilis, has been very disappointing, and is a broken reed when its assistance is most required.

During the past ten months, through the good offices of Dr. E. N. Davey, pathologist to the Gloucestershire Royal Infirmary, it has been possible to make arrangements for blood from patients at our county sanatorium to be submitted to the Verne test. I believe this test is being carried out at only one or two laboratories in this country, and, briefly, it consists in mixing the patient's serum with a preparation of resorcin and assessing numerically the resulting cloudiness in an elaborate and sensitive colorimeter. Up to the present over 200 tests have been made from my patients, and the least that can be said is that the results are extremely interesting and the method appears to be very promising. It is, of course, too early to pass judgement, but it certainly seems to be the best laboratory aid to diagnosis yet devised.

In the differentiation of diseased lung conditions there is a procedure which is possible only in an institution, but which is so valuable within its limited sphere that it is worthy of mention. It consists in taking an *x*-ray picture of the chest after the introduction into the bronchi of lipiodol. This is a poppy-seed oil heavily impregnated with iodine, thus rendering it opaque to *x* rays. The lipiodol may be introduced into the bronchi in various ways. The laryngologists do it through a bronchoscope. No one but a laryngologist would think of that. The usual method is by a tube inserted into the trachea through the crico-thyroid membrane. This is the method I have almost invariably employed, using the trocar and cannula devised by Dr. Chandler. It seems perfectly safe, and, provided the patient's confidence is obtained, is not unduly difficult. It is possible also, in some cases, to drop lipiodol over the base of the tongue and persuade the patient to inhale it. This may be very successful or a complete fiasco. Lipiodol is simply invaluable in the diagnosis of bronchiectasis; without it this diagnosis is very largely guesswork.

TREATMENT.

The history of the treatment of pulmonary tuberculosis is littered with the wreckage of discarded "specifics." These "specifics" obtained their temporary vogue largely because of two factors, which are not peculiar to the treatment of tuberculosis, and for which allowance must always be made in trying a new remedy. The first is the fight normally put up by the human body against any infection—a fight which in a proportion of cases is to be successful whatever remedy be used, or even no remedy at all. The second is the enormously important psychical factor. The hope which we are told "springs eternal" finds in any new treatment a stimulus and a justification. That explains why patients frequently say they are greatly improved when in fact they are not. It must also be—and this is a more difficult point—the explanation of an actual improvement, which later falsifies our hopes. But the influence of the mind on the body is a very large problem indeed, of which at present most of us see only the fringe.

At our county sanatorium we consider it a duty to examine as many as possible of the quasi-scientific measures which are confidently put forward from time to time. Calcium, for example, has been much lauded in treatment. We tried it in about fifty cases, giving a three months' course of subcutaneous injections of collosol calcium, reinforced by parathyroid extract by the mouth, and found its benefits not appreciable. Similarly antimony, garlic, pig's spleen, and numerous other drugs and extracts have had their enthusiastic advocates. Some of them are worth trying, but not one is specific or of general application. Sanocrysin, a double thiosulphate of gold and sodium, used intravenously, is still on its trial, and reports vary as to its virtue. It has the advantage of providing a line of attack, speculative though it may be, in cases where the doctor is at his wits' end to try to stay an advancing bilateral disease. It may produce definite symptoms of metallic poisoning, and, unfortunately, patients tend to lose weight while the treatment is in progress. We have had several cases where it was very successful, both in arresting active disease and in getting rid of tubercle bacilli from the sputum in chronic cases.

For the ordinary case of pulmonary tuberculosis employment of the general measures summed up in the term "sanatorium treatment" gives the best chance of recovery.

It is at times salutary for a doctor, who is freely prescribing treatment of all degrees of severity for his patients, to consider what line he would adopt if he were himself the patient. Putting that question to myself, I answer it without hesitation. Should it be my evil fortune to contract pulmonary tuberculosis I would start by going to bed under the best conditions possible, and staying there for six months. I would rely on no drug treatment whatever, unless possibly to meet some troublesome symptom, and I should expect to be well on the way to recovery at the end of that time. This factor of rest is of enormous importance. It is very striking, in patients with lung disease, and also a surgical condition necessitating prolonged immobilization—for example, spinal disease—to see how completely quiescent the lung condition becomes apparently as the direct result of this immobility. And rest is the factor which in ordinary practice is sadly neglected. The patients with raised temperatures who go out long walks in search of fresh air—their name is legion, and the results are disastrous. A patient with an oral temperature of 99.2° or over should spend the next day in bed. Among the insured population, and indeed all classes of the population, it is extraordinarily difficult to secure a sufficiency of rest, and the discipline of institutional life is almost always necessary even to approximate to what is needed.

Suitable food in reasonable quantity is another essential. It is an old saying that a hearty eater never takes tuberculosis. While this may be open to some doubt, there is no doubt whatever about the fact that a capricious and failing appetite is a serious bar to recovery. A well-balanced diet is best. It is not necessary to insist on an abnormal consumption of fats.

Fresh air day and night is now a well-recognized necessity; this need not be elaborated.

Regulated exercise and work have their undoubted place.

These are the essentials of sanatorium treatment, and they should be applied in every case, whether in or out of an institution.

Drugs are of value when indicated by symptoms. An irritating useless cough should be allayed, a productive cough may be aided by expectorants; suitable medicinal treatment aids a failing appetite. Drugs should not be used for night sweating. The proper cure for that is hyperoxygenation. Haemoptysis is an urgent symptom for which it is necessary to do something at once. Many drugs have been recommended, too many—a suspicious sign. Evidently no one of them can always be trusted. But whatever drug is used the essential thing is to follow a definite line with assurance. Put the patient to bed, propped up somewhat, and if he seems to require it, do not be afraid to give one dose of morphine, 1/4 grain, hypodermically. Its drawbacks have been greatly exaggerated. Allow only one reliable person at the bedside. An ice-bag is of no real value but may comfort the patient. I give either calcium chloride intravenously or haemoplastin intramuscularly if the haemorrhage is of any size. Both appear to give good results. Calcium lactate, 15 grains thrice daily, is subsequently given by the mouth for a fortnight in the hope of preventing a recurrence. But the only certain method of stopping haemoptysis is collapse of the affected lung by the induction of artificial pneumothorax. This is an indispensable weapon in the therapeutic armoury.

I am frequently asked what should be done for a pleural effusion. The proper course, if the fluid is in quantity, is to withdraw it and replace by air by means of a pneumothorax apparatus, and so continue the advantage gained from collapse of the lung. If no air replacement is proposed, and the amount is not causing distress, there is no reason why it should not be left for weeks. But if the effusion is sufficiently large to produce troublesome displacement of the mediastinal contents it should be partially withdrawn—only partially, however, as rapid expansion of the collapsed portion of lung must be avoided. And do not forget that the patient must be treated for the tuberculosis, of which the effusion is a symptom.

If the effusion is purulent in a tuberculous patient he would be a bold man who treated it as an ordinary empyema and excised a rib. The chances of a healthy scar are remote. A good treatment is to withdraw the purulent effusion and wash out the pleural cavity with weak iodine solution or other mild disinfectant. The wash-out is done from above, while the diluted pus is withdrawn from the base. It may take a gallon or two before the fluid runs through clear, and the lung is then kept collapsed by air. The process will probably have to be repeated more than once, but it gives good results, which cannot be said for ordinary surgical intervention.

I shall say nothing about tuberculin treatment, which is not being used to any extent in pulmonary tuberculosis, though its value is undoubted in genito-urinary cases. Ultra-violet light, the panacea of the moment, is of very problematical value in lung tubercle.

Surgical Treatment.

Mechanical and surgical methods of treatment are becoming commoner and more successful. The most important example is the collapsing of a diseased lung by the induction of artificial pneumothorax, a procedure which has already been mentioned.

The theory of this treatment is simple enough. It must be remembered that normally the lungs are kept expanded *beyond* their elastic tension by the virtual negative pressure in the pleural cavity. If air is introduced in sufficient quantity between the layers of pleura then the lung collapses completely. The virtue of collapsing and so resting a tuberculous lung is, I think, obvious. The lungs are constantly in a state of distension, and expand and contract twenty to thirty thousand times in the twenty-four hours. They have no chance of rest. And here is a method which as effectively rests a diseased lung as a splint rests a joint. The induction presents no special difficulties, but is not devoid of danger, and fatal accidents have been known to occur. The cases must be chosen with care, and *x*-ray films are essential. Unilateral cases are, of course, the ideal ones, but this limitation need not be strictly enforced. There is always a possibility that, in an otherwise suitable case, we may be defeated by adhesions.

The collapse should be kept up for at least two years, but patients may be capable of quite strenuous work with a completely collapsed lung. I am satisfied that in many cases collapsing a lung is veritably a life-saving procedure.

Phrenic evulsion, producing paralysis of the diaphragm on that side and the consequent obliteration of a large part of a diseased base, has a limited field of usefulness, but within that field is reliable, and its use might well be extended.

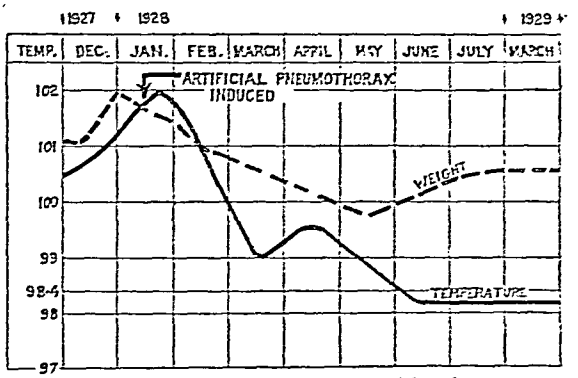

Chart showing effect of artificial pneumothorax on weight and temperature.

The only other method I shall mention is thoracoplasty. This is the most severe surgical proceeding for the treatment of pulmonary tuberculosis which is being used at the present time with any success. It is the logical sequel to an unsuccessful artificial pneumothorax. By a very extensive removal of rib the diseased lung is permanently collapsed and the disease arrested. In expert hand—and it requires very expert hands—the results are wonderfully good, considering that it is a somewhat desperate remedy for a desperate condition. Gravesen, whom I had the pleasure of seeing do the operation at the Vjelefjord Sanatorium, Denmark, is probably the greatest exponent of the method. When I saw him his figures were: 155 patients operated on; 42.5 per cent. fit for work two years and more after operation. Tudor Edwards, at the Cardiff Annual Meeting in 1928, gave the results of 59 cases; of these, 54 per cent. were either well or much improved. In a very recent private communication he tells me he has now done over 100 cases, with no deaths in the last series, and that the "apparent cures" show a higher percentage than the Cardiff figures. It must be admitted that these results are very remarkable.

To sum up treatment: reliance has to be placed chiefly on rest, food, and an abundance of oxygenation of the tissues; symptoms must be treated as they arise. I have purposely omitted any reference to such difficult and dangerous complications of pulmonary tuberculosis as laryngitis and enteritis. A course of sanatorium treatment is, as a rule, of real value: and the possibility should never be lost sight of that some of the modern methods of lung collapse may transform the whole aspect of a case.

Cases Illustrating the Importance and the Limitations of X-ray Examination.

Both patients were young men. No physical signs could be found in the chest in either. Neither case had sputum.

Case A (Fig. 1).—Diagnosed tuberculous peritonitis and admitted to a surgical ward at Standish House. The *x*-ray photograph of the lungs was taken as part of the routine examination, and shows typical miliary tuberculosis. The patient was consequently transferred to another institution. Two days later he showed signs of meningitis, and within a week he was dead.

Case B (Fig. 2).—There was haemoptysis of half a pint coming on a few hours after a blow from the starting handle of a back-firing bus. The condition was diagnosed by an expert radiologist after two examinations as extensive advancing tuberculosis. A month after this film was taken the man was allowed to return to work as a driver, and he has kept absolutely well since (two and a half years), putting on over 2 st. in weight.

In the one case *x*-ray examination settled a highly important diagnosis at once; in the other it was gravely misleading.

RETROGRADE NEEDLING.

A NEW TECHNIQUE FOR INSERTING RADIUM NEEDLES IN CARCINOMA OF THE TONGUE.

BY

K. H. PRIDIE, M.B., B.S., M.R.C.S.,

HOUSE-SURGEON, BRISTOL ROYAL INFIRMARY.

(*With Special Plate.*)

A NEW technique for inserting radium needles in carcinoma of the tongue has been devised to overcome the difficulties which are met with when needles are inserted by the usual technique.

Owing to the mobility of the tongue the movements of deglutition may displace needles inserted in the edges of a growth. In some cases the needles have been dislodged and swallowed, and in others they have been displaced, necessitating removal before the full dosage has been given. The back of the tongue, too, especially the epiglottic region, is very inaccessible, and great difficulty may be experienced in placing the needles in the growth and keeping them there. In addition, the deeper parts of the growth are too far from the needles to be affected by the radium.

The following case of carcinoma in the dorsum of the tongue illustrates the new technique. The growth was in the epiglottic region and the base of the tongue was infiltrated. The ulcerated area could not be seen from the mouth without the aid of a mirror. The radium needles used were shaped as shown in Fig. 1. They were threaded with Pagenstacher No. 2, knotted once.

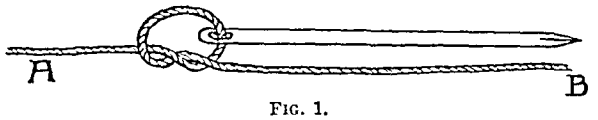

FIG. 1.

The tongue was drawn forward and a Greig-Smith abdominal needle was introduced into the space between the hyoid bone and the mandible, a finger introduced into the mouth guiding the needle so that it came out through the margin of the growth into the mouth. The end A of the thread attached to the radium needle was then threaded through the Greig-Smith needle, which was withdrawn through the skin of the neck and detached. By pulling on the thread the radium needle was drawn backwards into the growth till the point just disappeared. A small piece of rubber tube was threaded on the end A where it came out of the skin to indicate the depth of the needle in the growth. A piece of rubber tubing was threaded on to end B to protect the lip, and the ends A and B were knotted together loosely, forming a complete loop (Fig. 2). In a similar manner other needles were placed all round the growth.

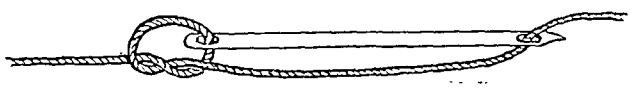

FIG. 2.

By pulling the ends A or B the needles can be made to travel either down into the deeper parts of the tongue and glands and finally out through the skin in the submaxillary triangle, or up in the mouth.

By transfixing the growth the deeper parts of it and the glands themselves may be treated after the needles have been for some time in the margin of the growth, and when supplies of radium are small a large area comes within reach of the needles when they are gradually pulled through the growth—for instance, one inch every three or five days.

A needle with two eyes (Fig. 3) is suggested for this technique, which has also been used with success in the treatment of new growths in parts of the body other than the tongue. For instance, when only four or five needles were available, a large sarcomatous mass on the parietal peritoneum was treated by this method, the needles being made to travel in four stages of one inch every three days.

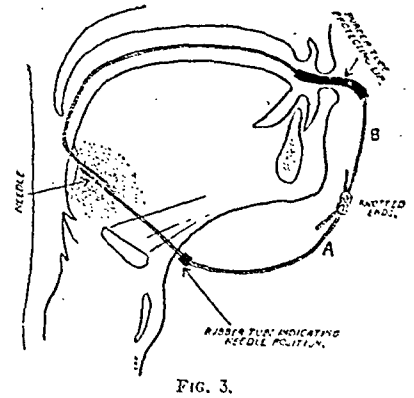

FIG. 3.

The advantages of this technique are:

1. The ease with which radium needles can be inserted in inaccessible regions.
2. A small quantity of radium can be made to act on a large area.
3. The position of the needles is always known and they can be moved with great ease and anchored where desired.

The disadvantages of the technique are:

1. Sepsis; there is always some pus and inflammation round the thread track.
2. Haemorrhage; the needle might puncture some vessel of large size, though this would be rendered unlikely by the use of two-eyed needles as suggested. In the cases treated hitherto there has been no trouble from haemorrhage.

The skiagrams reproduced in the Special Plate show radium needles *in situ* introduced by this technique.

THE PATHOGENESIS OF PULMONARY CAVITIES.

BY

S. VERE PEARSON, M.D.CAMB., M.R.C.P.,

RESIDENT PHYSICIAN, THE MUNDESLEY SANATORIUM.

(*With Special Plate.*)

THERE is a possible factor in the production of excavation in the lung to which hitherto little or no attention has been drawn. For some time I have felt that there is a certain amount of evidence indicating that a positive pressure of gas within an area of softening, or within a definite cavity already formed, helps to produce excavation. I have now been able to prove that this positive pressure occurs, because recently I was able to introduce a hollow needle safely straight into a large apical cavity, which needle was attached to the ordinary manometer of a pneumothorax apparatus, and I found a positive pressure of 16 cm. of water. From this cavity I extracted gas, and while able to reduce the pressure several centimetres I could not reduce it further, owing, apparently, to the fact that there was only an obstructed opening into the bronchus. Some two months later, on repeating the puncture of the cavity, I found that it was patent both on inspiration and during expiration. I append more precise details about this particular patient and send two photographs of his *x*-ray appearances, one taken in June, 1927, and the other in November, 1929.

There are several *a priori* reasons which support the likelihood of internal pressure as a factor in the pathogenesis of pulmonary cavities. Considering that cavities frequently have secretion in them, it seems reasonable to suppose that some of this may at times block the opening into the bronchial system. It is often taken for granted that a valvular opening through a hole in the lung surface into the pleural space, as occurs sometimes in spontaneous

pneumothorax, frequently gives rise to a positive pressure. A similar thing may be supposed to happen when there is a valvular opening into a cavity within the lung. But it is rather doubtful whether an appreciable positive pressure can arise in either case with an open epiglottis, since respiratory movements then simply oscillate around the atmospheric pressure—zero. It is when straining and coughing occur and the glottis is closed, with the production of a higher intrabronchial pressure, sometimes reaching many (for example, 20 or 30) centimetres of pressure, that a distinct, and occasionally dangerously high, positive pressure is produced. Manometric readings I have taken in the chest of an open spontaneous pneumothorax support this view.

In connexion with these points it must be remembered that the potential pressure in the uninjured pleural cavity itself is a negative one, and in some cases highly negative. I have found as low a pressure as −32 (inspiratory) and −14 cm. (expiratory) of water at the induction of an artificial pneumothorax. It is obvious, too, that the pulmonary tissue is of a soft and giving nature. This is increased sometimes in pulmonary tuberculosis, especially in those cases which show little tendency to fibrosis. Radiology demonstrates that cavities appear sometimes very quickly, and by the same means evidence can on rare occasions be brought forward to show that now and then they clear up surprisingly quickly. The fact that such a large proportion of cavities, especially of those which reach any appreciable size, are spherical is highly suggestive that internal pressure is a factor in producing excavation. I do not consider there is any evidence to lead one to suppose that gas-forming organisms produce gas in a cavity and hence set up positive pressures therein, though this is just a possibility in rare circumstances.

Mr. X., aged 33, was first admitted to the Mundesley Sanatorium in June, 1927. The first photograph shows considerable disease in the right lung, with several cavities of no mean size at the apex. There is also disease in the left lung, with small cavities at its extreme apex. The second photograph, taken on October 14th, 1929, shows an improved left side with an enormous apical cavity containing a minute quantity of secretion at the bottom, and below this partially compressed lower and middle lobes. This compression was artificially produced, its inauguration dating from October 4th, 1929. We watched the cavity grow during years, and have a series of photographs, some stereoscopic. Its extension shortly before October, 1929, was rapid.

When the patient was readmitted to the Mundesley Sanatorium on August 23th, 1929, and for many weeks afterwards, his condition was serious. He had considerable fever, but not much expectoration, only a few drachms. The outlook seemed bad. After consideration it was decided to see whether a right-sided artificial pneumothorax would compress the cavity. This decision was come to in spite of the fact that the left lung was affected, though now much better, and in spite of the fact that the two lower lobes on the right side were by this time functioning much better and the disease in them appeared healed to a large extent. Unfortunately the pneumothorax compressed only the healthier parts, the two lower lobes, and was followed rather quickly by a large outpouring of pleural fluid. Before the fluid arose, and feeling certain that the cavity was universally adherent to the chest wall, I punctured it in the second intercostal space anteriorly with a needle attached to a manometer, and found the pressures inside it +4 and +16. After withdrawing 250 c.cm. of gas these were reduced to close on zero and +11. After another 250 c.cm. was withdrawn the pressures were at 0 and +9. Then a further 250 c.cm., making 750 altogether, was withdrawn, but the pressures remained the same, 0 and +9. Now the ordinary intrapleural pressures taken before and at the end of several refills during the preceding weeks varied between −12 and +3. They were never positive at the beginning of a refill. Those at the initial induction were −12 and −3. On November 20th 550 c.cm. of fluid was withdrawn from the pneumothorax cavity; and again on November 30th and on December 11th between a pint and two pints of fluid were withdrawn. By the end of the year the patient's condition was greatly improved, the temperature had come down near to normal limits, and in the early part of 1930 the progress was continuing fairly satisfactorily.

On January 9th a second puncture was made into the cavity. On this occasion the pressures were found to be round about zero—namely, −5 and +5. The patient was rolled on to his left side to see whether any fluid in the cavity might reproduce a valvular opening. But no such effect resulted from the manœuvre, which only depressed the oscillations to −2 and +2. This, doubtless, was because the chief working lung, the left one, was compressed by the position of the patient, though the weight of the mediastinum falling away from the side in which the needle was situated would tend to make the oscilations bigger in a more ordinary case.

Dr. James Lawson first pointed out[1] that when the patient receiving an ordinary refill during the course of maintenance of an artificial pneumothorax turns from his side on to his back with the needle *in situ* the oscillations are rather less and the pressures rather higher. It was obvious that at this second puncture of Mr. X. there was no valvular opening.

At the time of writing apicolysis or thoracoplasty is under consideration. But with a poor resisting power and an unsound left lung, combined with the condition of the patient, which, though improved, is still far from satisfactory, these proceedings are not considered applicable, at all events during the next month or two.

DIVERTICULITIS, WITH PARTICULAR REFERENCE TO ITS DIAGNOSIS BY RADIOLOGY.*

BY

W. H. ROWDEN, M.B., CH.B.LEEDS, D.M.R.E.CAMB.

(*With Special Plate.*)

DIVERTICULA may occur or develop in any part of the alimentary canal. They may occur in the pharynx; in the upper, middle, and lower thirds of the œsophagus; in the cardiac or pyloric regions of the stomach, where, on radiological examination, an individual diverticulum may be mistaken for the crater of a gastric ulcer; in the first, second, and third parts of the duodenum; and in the region of the duodeno-jejunal flexure. Meckel's diverticulum of the ileum is well known. Gray, in his *Textbook of Anatomy*, states that Meckel's diverticulum is present in 3 per cent. of cases. Multiple diverticula scattered along the course of the jejunum and ileum have also been described.

An inflammation of any of these diverticula may be called a diverticulitis. But the diverticula, if small, do not, as a rule, give rise to symptoms, and most frequently they are found during the course of an *x*-ray examination of the alimentary tract made for some other reason. An inflamed diverticulum of the first part of the duodenum may, however, give rise to symptoms indistinguishable from those produced by a duodenal ulcer; and an inflammation of a diverticulum of the second part of the duodenum may be the cause, by direct extension, of those cases of pancreatitis the onset of which is difficult to explain.

The diverticulitis to which I wish in particular to refer is that which affects the colon, and more especially the sigmoid colon—colonic diverticulitis. Cruveilhier was the first to recognize the disease in 1849, and the condition was recognized and described also by Virchow in 1853. The first full description was that of Telling in 1908. According to James T. Case, the first case operated upon after previous radiological demonstration was published by Abbé, the radiological examination being carried out by Lewald. More recently, in this country, Spriggs and Marxer have published a paper in the *Lancet* (in May, 1927), and in America a recent communication is that of James T. Case, professor of roentgenology in the North-western University Medical School, Chicago.

Until the past few years the disease has been considered to be rare. The more frequent adoption of *x*-ray examination as an aid in the diagnosis of diseases of the colon has shown that the reverse is the truth: the disease is, in fact, more common than is perhaps generally realized.

The first step towards diverticulitis is the development of a condition of diverticulosis. That diverticulosis is not a congenital abnormality is, I think, proved by the rarity with which the condition is found in young people: it is essentially in adults over the age of 40 in whom we find evidence of diverticulosis. How are the diverticula

* A paper read before the Leeds and West Riding Medico-Chirurgical Society on November 22nd, 1929.

formed? I think a consideration of the physiology and of the muscular structure of the colon throws some light upon this question. The functions of the colon are four in number:

1. The conduction from the caecum to the rectum of the residue of food left after digestion has taken place in the small intestine, together with any material added in the colon.
2. The gradual absorption of water from this residue as it passes along the colon.
3. The secretion of mucin, necessary for purposes of lubrication and destruction of bacteria.
4. The excretion of certain heavy elements, such as lime, magnesium, iron, and mercury.

Observations of the colon on the *x*-ray screen show that the forward movement of the colonic contents as far as the splenic flexure is due almost entirely to the increasing pressure of the ileal fluids as they pass through the ileo-caecal valve. When the first part of an opaque meal arrives at the splenic flexure no further forward movement takes place for some hours; it is apparently in the ascending and transverse parts of the colon that the chief absorption of water takes place. This arrest of movement at the splenic flexure is especially noticeable on radiological examination of cases of duodenal ulceration without pyloric obstruction. On account of the rapid emptying of the stomach with which the presence of an active duodenal ulcer is associated, the first part of the opaque meal frequently arrives at the splenic flexure in less than three hours. On screen examination made three hours later it is usual to find that no further forward movement has occurred. In cases of duodenal ulcer, food, owing to its early arrival, is retained in the caecum and the ascending and transverse parts of the colon for a period greater than normal, and there is therefore a longer time allowed during which water can be absorbed. This may account for the constipation which is frequently associated with duodenal ulceration. Beyond the splenic flexure further movement of the opaque meal is produced by the passage along the transverse and descending parts of the colon of a peristaltic wave, which transfers the contents *en masse* to the sigmoid colon.

The role of the colon in the forward movement of its contents would appear in the main to be a passive rather than an active one. This conclusion is borne out by a comparison of the musculature of the colon with that of other parts of the alimentary canal in which active peristaltic movements are known to occur during the process of digestion. The stomach has strong internal and external coats, and a third, weaker, oblique coat; the small intestine has a strong internal circular and a strong external longitudinal coat. In the colon, on the other hand, there is only a weak internal circular coat, and the longitudinal layer is collected into three weak bands, the taeniae coli, with the exception of the sigmoid colon, where the longitudinal fibres are more scattered. Owing to its weak muscular development the colon, in man, is not able to exert or withstand any considerable pressure. For the efficient functioning of the colon it is intended by Nature that the colonic contents should be maintained in a soft condition. If more than 80 per cent. of water is absorbed the colon is unable unaided to expel its contents, and the voluntary abdominal muscles are called in to assist. The weak musculature of the colon is unable eventually to withstand the continual bringing into play of this additional force, with the result that the mucous membrane is gradually forced through the weakest points. That this is the probable method of formation of the diverticula is confirmed, first, by the fact that they occur most frequently in the sigmoid colon, where the greatest force is exerted by the contraction pressure of the abdominal muscles, and, secondly, by the fact that the majority of the diverticula are false diverticula—that is to say, they consist only of the mucous membrane and the submucous and peritoneal coverings of the bowel in contradistinction to the true diverticula which are formed from all coats. The false diverticula may be described as herniae of the colonic mucous membrane.

The condition of diverticulosis itself is not a disease. It is only when inflammatory changes occur in or around the diverticula that symptoms and signs of disease are manifested. The earliest stage in the formation of the diverticula has been named by Spriggs the prediverticular state. The prediverticular state is radiologically a clearly recognizable condition; it is found frequently in parts of the bowel distant from the original seat of diverticulitis.

Diverticulitis occurs chiefly in men over the age of 40. Of many cases, 75 per cent. have been men and 25 per cent. women. The age of the youngest patient was 43, and of the eldest 72; the average age was 61 years. All the patients had strong abdominal muscles, which, with one exception, were well covered with adipose tissue. I have not found the disease in an asthenic subject or in a patient with weak or poorly developed abdominal muscles.

The symptoms of *diverticulitis* may vary from a feeling of slight abdominal discomfort in an early stage of the disease to those of acute intestinal obstruction or acute peritonitis from perforation of a diverticulum. The discomfort in an early or moderately advanced stage of the disease may be limited to the left iliac fossa and the hypogastrium, or be referred to the upper part of the abdomen, and occasionally, in particular, to the right hypochondrium. The discomfort in the hypochondrium may give rise to a diagnosis of cholecystitis or duodenal irritation, and the true condition be overlooked. This is illustrated by the following case.

The patient, a well-built man of 43, complained of epigastric discomfort of three weeks' duration. He had lost a stone and a half in weight in two months. A radiological examination of the stomach and duodenum by means of an opaque meal was negative. In six hours a large portion of the opaque meal had reached the sigmoid colon. Six months later the patient was taken ill very suddenly with acute abdominal symptoms, which at operation were found to be due to a left pericolic abscess secondary to diverticulitis of the sigmoid colon. There is no doubt that if an opaque enema examination had been made the diverticulitis would have been discovered at the time of the *x*-ray examination. There was nothing, however, in the symptoms or signs to suggest disease of the sigmoid colon, except the rapid passage of the opaque meal along the bowel, evidence, in the light of future events, of an irritable condition of the colon.

Among other symptoms of *diverticulitis* are: increasing constipation and pain referred to the left iliac fossa during or following evacuation, intermittent or persistent pyrexia, and loss of weight. In the later stages there may be diarrhoea and the discharge of mucus per rectum; rectal haemorrhage is rare. Frequent and painful micturition occurs when the inflamed bowel becomes adherent to the bladder, and a vesico-intestinal fistula may result from perforation of the bowel. On abdominal palpation, tenderness is frequently present along the course of the descending colon. Some thickening of the bowel or an actual tumour may be palpated; a tumour situated above the crest of the left ilium is probably not due to diverticulitis. The symptoms and signs of perforation of a diverticulum are those of a perforated appendix referred to the left instead of the right iliac fossa.

A complete and definite diagnosis of diverticulitis can be made only by means of exploratory laparotomy and microscopical examination of an excised portion of the affected bowel or by means of *x*-ray examination. As the treatment is chiefly medical, *x*-ray examination is the method of choice. In cases of acute obstruction which necessitate operation it may only be possible to make a colostomy opening, the exact site and nature of the obstruction being ascertained by means of *x*-ray examination when the patient is sufficiently recovered from the effects of the obstruction to bear further manipulation.

There are two methods of *x*-ray examination—the opaque meal and the opaque enema. An examination by means of the opaque meal will give information as to the presence of diverticulosis, but it will not, as a general rule, provide evidence as to whether or not there is an accompanying diverticulitis. For the demonstration of diverticulitis an opaque enema is preferable. The two method may satisfactorily be combined.

I will not enter into a description of the method of procedure during the examination except to say that it is of the utmost importance that radiograms should be taken with the patient in the right and left oblique positions in

addition to the usual radiogram taken in the postero-anterior position. A single radiogram or a series of radiograms taken in the postero-anterior position will show advanced changes; but it is certain that with this position alone many cases of early disease of the colon, and especially early malignant disease, will be overlooked. Time and care in making the examination should not be spared.

Fig. 1 of the illustrations shows, in a patient of the *sthenic type, the appearance of a normal colon after the* injection of an opaque enema The chief points to be noted are: (1) the regular outlines of the haustral segmentation; (2) the haustral indentations on the superior and inferior aspects of the bowel, or on the internal and external aspects in the cases of the ascending and descending colon, are placed opposite to one another; (3) the overlapping of the coils of the sigmoid colon.

The earliest change in the appearance of the bowel in diverticulitis is an alteration in the haustration. The haustral indentations, instead of being placed opposite one another, alternate on each aspect of the bowel; secondary smaller indentations also make their appearance; the *indentations are regular in outline. This is the stage of* irritation. Fig. 2 shows this stage affecting a loop of the sigmoid colon.

In the next stage the haustral indentations, in addition to being spaced irregularly, become irregular in outline, producing an irregular V-shaped or W-shaped appearance of the bowel. This is the stage of thickening of the bowel wall. The third stage is the stage of the filling defect. The filling defect is produced by encroachment upon the lumen of the bowel by the thickened wall, resulting in a narrowing which, if the condition is untreated, will eventually lead to complete obstruction.

Frequently the three stages can be seen involving *different parts of the bowel in the same patient. This* is illustrated in Fig. 3, which shows a characteristic filling defect in the outline of the sigmoid colon; to the left of the filling defect is a portion of the bowel *in which* the haustral indentations are very irregular (stage 2), and to the right are very early changes of stage 1.

Fig. 4 shows a diverticulosis of the descending and sigmoid regions of the colon demonstrated by means of an opaque meal. It is not possible to say from this radiogram whether there is an associated diverticulitis. Fig. 5 shows the colon in the same case after an opaque enema: the enema shows definite evidence of the presence of diverticulitis in the first and second stages.

With regard to the *differential diagnosis, malignant* disease comes first and foremost. An early growth of the sigmoid colon may give rise to symptoms similar to those of diverticulitis in a patient who has lost very *little weight.* It should be an aim, in fact, to detect malignant disease before it has produced loss of weight. A growth does not produce loss of weight until it has reached a large size, and by then there are probably secondary deposits in other parts of the body.

The distinguishing points between the *radiological appearances of diverticulitis and of malignant disease of* the colon are:

1. Diverticulitis is associated with the presence of *diverticula in the neighbourhood of the deformity in the outline* of the bowel; in carcinoma, diverticula, as a rule, are not present.

2. Diverticulitis produces a *deformity which is* characteristic of the disease; the deformity produced by a growth varies according to whether the growth is of the ulcerating, papillomatous, or encircling *ring type.*

3. Diverticulitis usually involves a considerable length of the bowel, whereas the length of bowel involved by carcinoma is short.

Fig. 6 shows (after an opaque enema) the appearance produced by an advanced growth of the sigmoid colon.

Fig. 7, by way of contrast, shows a *spasmodic* deformity *in the outline of the sigmoid colon due to the presence* of an early malignant ulcer. Fig. 8 shows a filling defect in the outline of the descending colon produced by a ring carcinoma. This patient was *examined on account* of the presence of a tumour at the level of the crest of the left ilium, with a view to determining if the tumour was due to diverticulitis or a growth. The appearance of the filling defect is characteristic of a ring carcinoma; on microscopical examination after removal the tumour was found to be an adenocarcinoma. *In Fig. 9 is shown the appear*ance of the colon after an opaque enema in a case of *ulcerative colitis. There is complete loss of haustration.*

In conclusion, the possibility of a double pathology must not be lost sight of. It is not uncommon to find disease of *the gall-bladder in cases of diverticulitis, and it is pos*sible for a growth of the caecum or the ascending colon, or the transverse colon, to be associated with the presence of diverticulitis of the sigmoid colon. *A double pathology should* always be looked for. The advanced age of the patient in most of my cases of diverticulitis would appear to show that the presence of this disease does not predispose towards the supervention of malignant disease of the affected part of the bowel

THE SIGNIFICANCE OF SUBCLAVICULAR PAIN IN LESIONS NEAR THE DIAPHRAGM.

BY

ZACHARY COPE, M.S., F.R.C.S.,

SURGEON TO ST. MARY'S HOSPITAL, PADDINGTON.

ONE of the commonest and most perplexing problems of diagnosis is that of distinguishing between a supra- and an infra-diaphragmatic lesion. The purpose of this note is to point out the helpful significance of one symptom—that is, pain in the subclavicular fossa. The occurrence of this symptom in cases which are otherwise doubtful generally signifies that the disease is above the diaphragm. So far as I am aware no medical textbook has yet called attention to this point, which has been of great value to me in the diagnosis of difficult cases during the last ten years.

It is well known that the *common source of origin of* the phrenic and the descending cutaneous cervical nerves is responsible for pain being referred to the top of the corresponding shoulder from the diaphragm. It is less well recognized that the anterior or posterior part of the shoulder is affected according to whether the irritation of the diaphragm affects the anterior or the posterior part of the muscle. Subclavicular pain would therefore be caused by irritation of the extreme anterior part of the diaphragm. With a diaphragmatic pleurisy any effused fluid tends to collect posteriorly in the recumbent patient, and any friction and consequent pain would occur anteriorly. In pericarditis also any spread of the inflammation to the *diaphragm would usually irritate the anterior portion.* Whether or no this is the correct explanation of the cause of subclavicular pain the clinical fact is witnessed by the following illustrative cases.

CASE I.

A young man awoke on the morning of August 22nd, 1920, with acute pain in the right subclavicular fossa. He had a shivering fit, vomited a few hours later, and when seen by his doctor (Dr. Weir of Brondesbury) a few hours later there was fever of 104° F. and pain in the right hypochondrium. His condition did not improve under treatment, and I was asked to see him on August 25th. When I saw him his temperature was 104°, and he was sweating. There was some deep tenderness in the right hypochondrium and right iliac region, and the patient still complained of pain in front of and below the right clavicle. There was no dullness in the chest, but some fine inspiratory crepitations were heard on the anterior and lateral aspect of the right lung base. In this case there was for a time some doubt as to whether the abdominal pain was due to appendicitis. The crepitations and the subclavicular pain made it clear that the condition was due to diaphragmatic pleurisy, and subsequent events proved this to be correct.

CASE II.

A middle-aged woman was taken ill the last week in December, 1922, with a cold in the head and pain in the limbs. On December 30th she developed a sudden pain in the right side of the abdomen and the right side of the chest. There was also pain felt in front of and below the right clavicle. She vomited several times. Dr. Dunstan (under whose care she was) thought he heard some fine crepitations at the right lung base. When I saw her, on December 31st, the alae nasi were working and there was

tenderness over the right lower ribs in front and over the right hypochondrium. There was no dullness, and no adventitious sounds could be heard at the right lung base. There was no abdominal hyperaesthesia. The diagnosis of diaphragmatic pleurisy was made and confirmed later by the development of dullness at the base of the right lung.

CASE III.

W. M., aged 20, on March 8th, 1921, suddenly felt a stabbing pain under the left collar-bone. The pain only lasted for half an hour, but came on again that night, and seemed to be worse on taking a deep breath. It gradually got worse, and by March 19th was fairly continuous. There was giddiness, vomiting, and also epigastric pain. When admitted to St. Mary's Hospital on March 19th the pain had become more precordial, and there was cyanosis. On March 21st a faint pericardial rub was heard just outside the sternum in the third left intercostal space. A few days after admission the patient still had a little left subclavicular pain.

CASE IV.

A man, aged 53, consulted me at the Bolingbroke Hospital (at Dr. Bradlaw's request) on account of severe gastric symptoms which proved to be due to a penetrating ulcer of the lesser curve of the stomach. I performed partial gastrectomy, and for a fortnight recovery was uneventful. The patient then complained of pain under the right clavicle, and a day or two later he had an attack of extreme pain in the right side of the abdomen, accompanied by sweating and vomiting. The pain under the right clavicle continued and was worse when he took a deep breath. When I examined him a little later there was extreme tenderness and muscular rigidity in the right hypochondium, to such a degree that the resident officer at first thought there might have been a leakage from the stomach. But the tenderness was strictly limited to the right of the middle line, and there was not the slightest pain elicited on pressure to the left of the midline. This strict limitation of tenderness and rigidity, together with the presence of tenderness over the right lower chest and the complaint of subclavicular pain, made me think that the pain was one referred from the upper surface of the diaphragm. I concluded that there had been a small pulmonary infarct which had caused diaphragmatic pleurisy, and this view was borne out by the gradual clearing up of the symptoms. All during the time of the pain, except at the very onset, the patient had been able to take fluid and semi-fluid food well. I saw him a month later and he was perfectly well.

CASE V.

A man of 67 was admitted to St. Mary's Hospital in November, 1929, with symptoms of perforated gastric ulcer. At the operation I found general peritonitis due to leakage from an ulcer on the lesser curve of the stomach. The perforation had been sealed up and all that remained to be done was to oversew the ulcer. Convalescence was uneventful for two weeks, when the patient complained of pain in the left subclavicular region. I at once told the house-surgeon to be on the look out for left basal pleurisy. The pain continued and fever developed, and when I examined the chest a few days later there was decided dullness at the left base. An *x*-ray photograph of the chest did not show any evidence of subphrenic abscess. The dullness at the left base increased, and I explored the left chest and removed several ounces of clear fluid. Though he was better after this there was still subclavicular pain, and I was not perfectly satisfied that there was no collection of pus under the diaphragm. Therefore, under local anaesthesia, I made a small incision into the upper abdomen and explored the left subphrenic space. It was perfectly normal. I later removed more fluid from the left chest and the condition gradually improved.

These cases, and others like them, have guided me to the conclusion that in cases of doubtful diagnosis subclavicular pain almost always indicates a lesion on the upper surface of the diaphragm. In those rarer cases in which an abdominal lesion causes subclavicular pain there is always some clear lead to the diagnosis from definite signs in the lower abdomen. Thus I have known slight left subclavicular pain consequent on the perforation of an ulcer on the anterior wall of the stomach; presumably the contents impinged against the anterior part of the diaphragm. In the same manner the blood from a ruptured ectopic gestation may flood up to the diaphragm and cause pain over and below the clavicles, but here other symptoms help to the diagnosis. Once also I have known subclavicular pain caused by appendicular peritonitis in which some lymph was deposited in front of the liver and caused irritation of the lower and anterior part of the diaphragm. But in these cases the other abdominal symptoms and signs were sufficient to prevent confusion in diagnosis.

THE HEREDITARY FACTOR IN ASTHMA AND OTHER ALLERGIES.

BY

GEORGE W. BRAY, M.B., CH.M.*

(From the Asthma Clinic at the Hospital for Sick Children, Great Ormond Street.)

THE material on which this communication is based consisted of 200 consecutive unselected cases of asthma attending the asthma clinic at the Hospital for Sick Children, Great Ormond Street; these have been investigated with regard to sex incidence, age at onset of asthmatic symptoms, and the presence or absence of allergy in other members of their families. The manifestations particularly inquired for were: asthma, hay fever, eczema, urticaria, and migraine. Due care was taken to exclude such "positive" cases as asthma commencing late in life or in the presence of known renal or cardiac disease; sneezing of an occasional, non-seasonal, and non-environmental nature; eczema of but short duration or of presumably occupational etiology; urticaria occurring only occasionally as a child and at extremely isolated instances in later life; or migraine that did not give more than one of the characteristic ocular, cerebral, or abdominal symptoms.

In all, 4,152 relatives were considered—an average of 20 per patient. As no patient attends the hospital after the age of 12 years, the 200 cases comprise children whose asthma had its onset during the first decade of life. The homes are distributed over most of the London districts, but principally to the east and north, and some of the cases came from provincial towns. Only about 5 per cent. of the children were of Jewish parentage, and in this one respect the series differs from that described by Peshkin of 100 consecutive cases of asthma in children on the east side of New York, where 92 per cent. were of Jewish parentage.

SUMMARY OF RESULTS.

	Males.		Females.		Total	
	No.	Per cent.	No.	Per cent.	No	Per cent

A = Affected. T = Transmitter. U = Unaffected.

* Working with a grant from the Asthma Research Council.

Age Incidence.

The age at onset of first symptoms during the first decade appears greatest during the first year of life, and declines progressively towards the tenth year (Chart 1). Analyses of the cases with regard to the presence or absence of allergic manifestations in other members of the family bear out the same fact. The small peak during the second year in cases with bilateral inheritance is negligible considering the small number of cases showing such heredity.

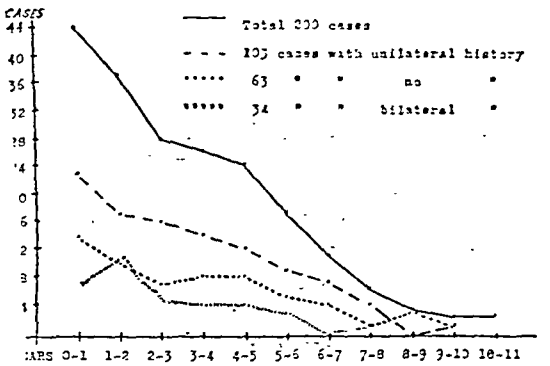

CHART 1.

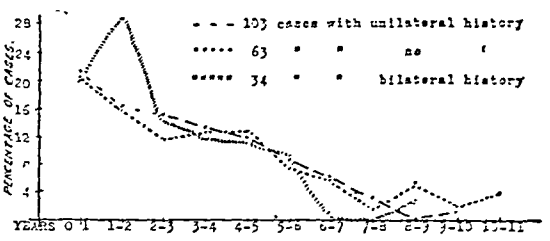

CHART 2.

In Table I the relationship between age, sex, and family history is depicted. In Table II the age at onset in this series is compared with a series of 197 children described by Bullen, 100 by Peshkin, and 135 by Coke, the onset of whose symptoms was during the first decade. If we consider the percentage of total cases in each history group per year (as in Chart 2) we notice that the age of onset of symptoms runs practically identically in the three history groups. Most observers have shown, in dealing with cases at all ages, that the greater or more complete the inheritance, the earlier the age at which symptoms will have their onset. In this series of cases with onset during the first decade about 21 per cent. develop symptoms irrespective of any hereditary influences, and during the remainder of the decade the groups continue to run fairly parallel. In other words, heredity plays no part in determining the age at onset of symptoms during the first decade.

Sex Incidence.

The sex incidence in this series was: males 72.5 per cent., females 27.5 per cent. Rackemann, in 90 children, found 73 per cent. males and 27 per cent. females. Comby, in 75 children, noted 57 per cent. males and 43 per cent. females. Coke's 135 children comprised 60 per cent. males and 40 per cent. females. Among 4,152 relatives the sexes were fairly evenly distributed—males 51 per cent., females 49 per cent.

The total affected persons in the whole group were: males 342, females 255. If we subtract the total number of patients from these figures we find that the sex incidence among the remaining affected relatives is practically identical—males 197, females 200. These figures closely approximate the 400 cases in adults described by Walker, where 198 were males and 202 were females. In adults similar figures are given by other observers: Bullen in 265 cases found 49.4 per cent. males and 50.6 per cent. females; Coke in 350 cases found 178 males and 172 females at all ages, but 71 males and 101 females from puberty to the menopause.

It is thus apparent that from birth to puberty the sex incidence of males to females is nearly 3:1, whilst from puberty onwards the incidence is less than 1:1. Puberty, therefore, is a definite decisive milestone toward which a great number of males must improve and beyond which a greater number of females develop symptoms. There is another possibility that at this point the allergic tendency manifests itself in another form. Obviously puberty must exert some beneficial effect upon the symptoms in the male and some deleterious effect upon the female. Such a fact is in full accord with the life-histories one often hears in these asthmatics. How often does the father say he suffered from asthma till he left school or commenced to work, or the mother assign the onset of her asthma to post-school years or marriage! When we consider the transmitters—sons or daughters of allergic parents who, whilst not showing any symptoms of allergy in themselves, have a child or children who manifest the allergic state—we note that the proportion of females to males is as 2:1. Also in cases with a unilateral family history we notice that transmission is twice as often through the mother's side as through the father's. Adkinson, even though she did not find asthma inherited more frequently from either parental side, did note that twice as many women as men inherit asthma from the maternal side, and that 25 per cent. more women inherit asthma directly from the parents. In addition, in tabulating the inheritance particulars, we note that there are twice as many affected with allergy where the male is unaffected and the female has or may transmit the tendency as when the male is affected or a transmitter and the female quite free.

Such figures suggest that inheritance of allergic manifestations is twice as frequent through the female as through the male, and that twice as many offspring are likely to be affected when the female transmits. Of the offspring, over twice as many males as females are likely

to be affected before puberty; the probability of a speedy recovery about puberty is much greater in the boy than in the girl; and the chance of developing allergic manifestations after the age of puberty is more probable in the female than in the male. Migraine appears to be far more common among female relatives, especially in the same family, whilst asthma, eczema, and urticaria appear to be more common in males. Four cases of ichthyosis occurred in males, whilst of a total of five cases of angio-neurotic oedema four were males. Hay fever appears with about equal frequency in males and females among the relatives, but more in adults than in children.

Family History.

A positive family history of allergy was determined in 68.5 per cent. of cases. In 51.5 per cent. the history was unilateral, whilst in 17 per cent. it was bilateral. Comparable figures have been given by Rowe, who in 110 cases of asthma in patients under the age of 20 found that 51.8 per cent. gave a unilateral family history and 19.1 per cent. a bilateral one. At the same time it must be appreciated that some of the cases in which a negative family history is recorded may in reality be positive, or would have been positive had the members lived longer, or come in contact with the allergen to which they may be sensitive, or might develop a sensitivity—as, for example, a person showing no evidence of allergy in England, but who would manifest sensitivity in America in a ragweed environment.

In numerous cases members of families have gone abroad, and all trace of them has been lost, a fact that may reduce the percentage incidence. In addition, the figures given include all persons of any age, whether dead or alive; this necessitated the inclusion of a lot of infants who were under 1 year of age at the time of death, four out of five of which, even in the presence of a strong hereditary tendency, would not have developed any symptoms before the age at death.

Among presumably normal persons Balyeat determined the presence of a positive family history in 8.3 per cent. of the relatives of 1,117 students; Spain and Cooke in 7 per cent. of 115; and Cooke and Van der Veer in 14.5 per cent. of 68 families.

Hereditary Transmission.

From a consideration of the figures given it is obvious that one cannot consider the transmission of specific diseases from parent to child, as one can such an anatomical peculiarity as lobster hand, since it is only a tendency or diathesis that is transmitted. Adam aptly states: "Asthma is no more hereditary than phthisis or gout; the tendency—the soil—is inherited; whether the disease will develop depends on nurture." Nevertheless most observers are agreed that this tendency is transmitted as a Mendelian dominant factor. The main dissenters from this view are Buchanan, who says that "essential asthma in its familial appearance follows none of the known laws of heredity," and Adkinson, who, in a paper restricted to the discussion of asthma as an inherited character, states that transmission is as a Mendelian recessive, and does not attempt to probe the larger problem of inheritance of sensitization to protein in general.

The tendency to manifest allergic symptoms is definitely transmitted. Whether the person will develop any manifestations or not depends on numerous external factors other than heredity—as, for example: (1) Extent of exposure to various proteins. Peshkin's children slept on rabbit hair, to which 49 per cent. were found sensitive. Balyeat, in a similar series, found 43 per cent. sensitive to feathers and only 2 per cent. to rabbit hair. (2) Extent of previous lung damage. Children with badly damaged lungs frequently develop asthmatic symptoms independent of heredity, but in the presence of heredity such symptoms appear to develop earlier than would otherwise be the case. Many parents assign the onset of a child's asthma to a previous pneumonia, whether of a simple nature or following measles and whooping-cough. (3) The presence of focal infections—in children, especially enlarged tonsils and adenoids, and dental caries.

Among other points may be mentioned constipation, nervous or endocrine disturbance, achlorhydria or hypochlorhydria, colouring (pale skin, blonde hair, blue-eyed type).

Historical.

The hereditary factor in asthma has been recognized for many years. Sir John Floyer (1698) states: "As my asthma was not hereditary from my ancestors, so, I thank God, neither of my two sons are inclined to it, who are now past the age in which it seized me." Cullen, in his *Practice of Physic* (1784), and Ryan (1793) both suggest the possibility of hereditary transmission. American authors, as Eberle (1831) and Goode (1836), maintained that hereditary transmission was the generally accepted opinion. Andral (1839) mentions heredity as one of the prime factors predisposing to asthma. Ramadge (1847) gives an instance in which the disease appeared in four generations. Salter (1860), in a study of 35 cases, determined a positive family history in 38 per cent. Stevenson (1879) described how he inherited his asthma from his paternal grandmother. Geddings (1883) states "that this tendency is hereditary in nature is conceded by every prominent writer on asthma." Osler (1884) speaks of the hereditary tendency manifested by allergic dermatoses.

The first important contribution to this study in the present century is that of Czerny (1905), in discussing asthma and other allergies in his exudative diathesis. Drinkwater (1909) records a very impressive family history. The more recent investigators and their conclusions are tabulated in the following summary.

OBSERVATIONS ON PERCENTAGE INCIDENCE OF POSITIVE ALLERGIC FAMILY HISTORY IN VARIOUS MANIFESTATIONS OF ALLERGY.

Normals.

Balyeat: 1,117 cases; 8.3 per cent.
Spain and Cooke: 115 cases; 7 per cent.
Cooke and Van der Veer: 68 cases; 14.5 per cent.

Allergy.

Balyeat: 1,217 cases. Believes Mendel's law followed as single dominant. With bilateral history symptoms manifested in first decade in 58.6 per cent., in second 10 per cent., after 30, 0.3 per cent. With unilateral history 32.3 per cent. in first decade, 30.8 per cent. in second.
Smith: 94 relatives in five generations; 56.2 per cent. suffered from some form.
Unger: 189 cases; 19 per cent.

Food Allergy.

Rowe: 175 cases; 68 per cent.

Asthma.

Adam: 20 per cent. Only tendency or soil that is inherited.
Adkinson: 400 cases; 48 per cent. Nature of inheritance is as recessive. 191 protein sensitive, 52 per cent.; 209 negative, 41 per cent.
Berkhart: 16 per cent.
Buchanan: Follows none of known laws of heredity in appearance.
Bullen: 500 cases; 39.4 per cent.
Coke: 350 cases; 46 per cent.
Drinkwater: 20 relatives in four generations; 10 affected, 10 unaffected.
Goodhart and Spriggs: 21 per cent.
Rackemann: 150 cases; 58.7 per cent. in sensitive cases, 10.5 per cent. in non-sensitive.
Rowe: 234 cases; 58.4 per cent. 45 cases; 62.2 per cent.
Salter: 35; 38 per cent.
Van Leeuwen: 49 cases; 63.6 per cent.

In Children Only.

Bullen: 235 cases; 50.7 per cent.
Comby: 75 cases; 58 per cent. hereditary and similar; 46 per cent. and dissimilar.
Peshkin: 278 cases; 42.5 per cent. 40 per cent. in sensitive group, 45 per cent. in non-sensitive.
Rowe: 110 cases under 20; 70.9 per cent. 19.1 per cent. with bilateral history, 51.8 per cent. with unilateral history.
Schloss: 80 cases; 47 per cent.

Asthma and Hay Fever.

Spain and Cooke: 462 cases; 58.4 per cent. 7.3 per cent. with bilateral history, 51.1 per cent. with unilateral history. In 549 families with 1,889 children, where there was a bilateral family history 71.6 per cent. eventually develop symptoms, with unilateral history 51.1 per cent.
Cooke and Van der Veer: 504 cases; 48.4 per cent. Believe Mendel's law followed as single dominant, but may be multiple.
Kahn: 100 cases; 80 per cent.
Rackemann and Colmes: 25 per cent.

Allergic Dermatoses.

Piness and Miller; 345 cases; 41 per cent.

Urticaria.

Menagh: 260 cases; 32.6 per cent.
Rackemann and Colmes: 25 per cent.
Rowe: 20 cases; 55 per cent.

Angioneurotic Oedema.

Ensor: 33 of 80 persons in five generations; 41 per cent.
Osler: 22 of 36 persons in five generations; 61 per cent.
Rowe: 14 cases; 43 per cent. gave history of similar complaint.
Whiting: 265 cases; 53 per cent. 110 in family groups comprising *total of 207 individuals.*

Eczema.

O'Keefe and Rackemann: 239 cases; 28 per cent.
Rackemann: 36 per cent. children, 59 per cent. adults.
Rowe: 16 cases; 69 per cent.

Migraine.

Bramwell: 50 per cent. cases show direct transmission, mostly through mother.

Buchanan: Transmission is expression of *Mendelian phenomenon.* Unilateral history in 100 families with 631 children, 22.6 per cent. had migraine. No history in seventeen families with 115 children, 26 per cent. had migraine. Bilateral history in three families with 15 children, all had migraine.

Diamond: 35 cases. Nearly all gave positive family history with transmission in main through mother.

Rowe: 30 cases; 86.6 per cent.

Tileston: 50 per cent. cases show direct heredity, even for three *to four generations.*

Ball: From 1,000 unselected family histories—261 cases migraine; associated with migraine in other members in 45.9 per cent. 162 cases asthma; associated with migraine in 37 per cent. 91 cases hay fever; associated with asthma in 49.4 per cent., and with migraine in 38.4 per cent. Eczema; associated with eczema in 21.3 per cent. and with migraine in 40.9 per cent.

Established Facts.

The main facts which have accrued from the vast amount of consideration that has been given to the subject of the transmission of the tendency to exhibit allergic manifestations may be summarized as follows:

1. The allergic diathesis is transmitted as a Mendelian dominant.

2. *The greater the heredity the earlier are symptoms mani*fested.

3. The earlier in life the individual becomes sensitive the greater the tendency to multiple sensitization.

4. Asthma, hay fever, eczema, urticaria, angioneurotic oedema, and migraine appear to be *intimately correlated,* and to be interchangeable.

5. *A child born in a family with a pure hay fever lineage* is much more likely to be affected with hay fever than with asthma, and vice versa.

6. Where several members of *one family are affected,* sensitization is not identical as regards the specific proteins, nor are the clinical types of allergy or the symptoms displayed in each type themselves *identical in different members of the* same family.

The main additions deduced from this study are:

1. Puberty must *exert some beneficial effect* upon the symptoms in the male and/or some deleterious effect upon the female, for before puberty the incidence of males to females is over 2:1, whilst from puberty onwards it is less than 1:1.

2. Heredity plays very little part in *determining the age* at onset of symptoms during the first decade.

3. Transmission appears to be twice as frequent *through the female as through the male,* for (*a*) when there is a unilateral family history it is twice as frequently on the mother's side as the father's; (*b*) when the parents are unaffected the transmitter is twice as often the female; (*c*) when the male is unaffected and the female has or may transmit the tendency, twice as many are affected with allergy as when the male is *affected or is a transmitter* and the female is quite free.

4. A positive family history of allergy is present in about 70 per cent. of cases of asthma in children—in over 50 per cent. unilateral, *in nearly 20 per cent. bilateral;* 10 per cent. appears to be the maximum incidence in the families of presumably normal persons.

In conclusion, I would like to convey my thanks to the physicians at the Hospital for Sick Children for kind permission to make use of cases under their charge, as well as to the Asthma Research Council, under whose grant these investigations have been rendered possible.

NOTES ON ADDER BITE.

BY

MARK R. TAYLOR, M.R.C.S., L.R.C.P.,

REGIONAL MEDICAL OFFICER, MINISTRY OF HEALTH.

SOME years ago Sir Thomas Oliver published an article on adder bite in the *British Medical Journal* (December 9th, 1922, p. 1115), and at his request I sent some notes, published on March 13th, 1923 (p. 375), on a case I had seen and on others of which I had knowledge. Since then I have seen the two cases now to be described.

CASE I.

About four years ago I examined, with Dr. Ryder Richardson of Saxmundham, Suffolk, a child, aged about 3 years, who had been bitten about two hours previously. The bite was on the dorsum of a terminal phalanx of a finger. Before our arrival the district nurse had applied silver nitrate so effectively that the punctures were invisible. The child was comatose, pallid, sweating, and almost pulseless. Dr. Richardson injected strychnine, incised the area of the punctures, and rubbed in permanganate. By that time the hand and arm were much swollen and discoloured. Later he informed me that the child had recovered, after suffering several days' severe illness, during which the arm and side of the chest became very swollen and turned all the colours of the rainbow.

CASE II.

In March, 1927, a strong and healthy man of 57 (a patient of Dr. Barber of Sandown, Isle of Wight) was out adder hunting, and while catching an adder in some rough grass he thought his finger had been pricked with a bramble. About twenty minutes later he felt pain in the hand and noticed that it was swelling. The swelling spread up the arm and over the chest, and he began to feel nausea and giddiness; he became so sleepy that he had difficulty in getting back to his farm. Forty-five minutes after he was bitten he was put in a car and taken to the doctor, who injected a stimulant. Violent diarrhoea set in, but the patient was able to walk to the car, in which he was driven home. During the journey he had hallucinations, seeing "large girders being erected for the construction of a skyscraper." When he arrived home he was unable to walk upstairs, and on getting into bed he had a rigor and his breathing was stertorous. Vomiting and diarrhoea continued for some hours; his face was swollen and purplish; the arm continued to swell for three days, and was quite lifeless. He suffered intensely from thirst and drank large quantities of barley water and lemonade, but passed no urine for seventy-five hours after he had been bitten. When, at the end of a fortnight, he was able to get up, he felt very weak and found that his right leg was slightly swollen. The swelling of the right arm persisted for some nine months; he could use it only with difficulty, and the movements were limited apparently by the oedema.

I saw the patient in August, 1928, some seventeen months after the accident. He was getting electrical treatment and massage.

The arm was not swollen, but movements of the shoulder were stiff and painful, and he could not close his fist. Deep pressure behind the middle third of the clavicle produced pain.

I saw him again in December, 1928, when he had returned to work. He complained of some loss of grip in handling his tools. He could just make his fingertips touch his palm, and complained of pain on forcible flexion of the fingers. During the first year most of his inability to move the arm was due to the oedema. When I saw him there seems to have been some paralysis as well.

The following cases have been brought to my notice:

CASE III.

A child was admitted to the Royal Victoria and West Hants Hospital, under Mr. Kinsey-Morgan, having been bitten the previous day; his arm was greatly swollen and hard, and Mr. Kinsey-Morgan made multiple incisions and drained the brawny area. This treatment, he says, gave dramatic relief, and the child was much better in two days, by which time antivenin had been obtained and 15 c.cm. administered. The child was in hospital eleven days.

CASE IV.

Dr. B. of Bournemouth, lying in some long grass, was bitten on the thumb; he thrust out instinctively, and was struck again on the other thumb. A few hours later intense vomiting and diarrhoea, with collapse, set in. He incised the puncture at once and later saw a doctor, who applied strong ammonia. The arms were much swollen and purplish, and the pain was very severe; owing possibly to cauterization by the ammonia the skin of both thumbs ulcerated and took several months to heal. One thumbnail was lost.

Recently, in the *Daily Telegraph*, a correspondent extolled a wonderful cure for adder bite discovered by "Brusher Mills" of Lyndhurst. "Brusher Mills" was a well-known character in the New Forest; he died in 1905. One of his chief activities was collecting adders for zoos and laboratories; he prepared his "cure" by extracting the fat from adders, boiling it and straining it through a scorched cloth, letting it set like a jelly. It is said that he used to charge a guinea an ounce for this product. He professed to have no fear of adder bite as long as he had some of the fat with him. "Brusher's" remedy was a form of sympathetic magic, which appears to be world-wide, and is practised by Australian aborigines, Hottentots, and many other primitive people.

References to adder bite in medical literature seem to be very few, and Professor Francis Fraser very kindly supplied me with particulars of his father's (Sir T. R. Fraser) writings on snake venom. Madame Physalix, in her book *on Venomous Snakes*, gives very little information about English adders. Dr. Leighton (*Life History of British Serpents*, p. 130) refers to a fatal case of adder bite recorded in the *British Medical Journal* of July 15th, 1893 (p. 114); in this case a boy of 11 was bitten on the finger, had *severe symptoms—oedema, discoloration*, and general collapse—and died about thirty-six hours later. Dr. Stradling (Watford), in a letter to the *British Medical Journal*, July 29th, 1893, stated that he believed this to be the fourth fatal case vouched for by a competent authority. Dr. Leighton cites another fatal case which occurred in 1901, in a boy aged 4½. It is commonly said that the sting of adders is worse in the spring; it may be that during their winter sleep they store up poison, and thus have an increased or even a more concentrated supply for their first bite. It seems unlikely, however, that a supply of poison would be formed during the viper's hibernating period.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

INFECTION WITH THE BACILLUS ENTERITIDIS RESEMBLING PSITTACOSIS.

OWING to the number of cases of psittacosis reported in medical and lay papers, and the fact that it is not generally known that members of the *Salmonella group* may give rise to an illness resembling typhoid and paratyphoid fever, the following case is worthy of record.

A previously healthy business man, aged 52, noticed an "uncomfortable feeling," which he referred to the upper part of the abdomen. When first seen his temperature was 97.8°, but the next day it rose to 102°, and for sixteen days his temperature ranged between 102° in the morning and 104° in the evening. The respiration was not hurried, and the pulse varied between 98 and 104. There was severe sweating at times. On the sixth day of the illness a patch of dullness and tubular breathing was found over the right apex posteriorly. On the eleventh day there was cough and purulent *expectoration*, and three days later medium crepitations were heard over the lower lobes of the lungs. On the twenty-fourth day of illness, when his temperature was 98.6°, he developed a *left-sided* pleurisy; two days later this was followed by pericarditis, and within twenty-four hours there was an extension of the cardiac dullness upwards and to the left. The respirations were now 40, and the pulse 120; the heart sounds were very feeble, and triple rhythm was heard. The systolic blood pressure figure was 65. The face was dusky, and the lips and ears were cyanosed. The patient lay in a state of semi-coma. His condition was grave, and for six days he was between life and death; then his blood pressure rose to 100, his pulse and respirations became less rapid, and he made a slow recovery. During his illness there were no rose spots and no enlargement of spleen. Constipation was present throughout the illness, and required aperients and enemas.

The blood serum showed positive agglutination with *B. enteritidis* in dilutions of 1 in 50; ten days later it gave a positive reaction to the same bacillus in dilutions of 1 in 25. No Salmonella or *B. typhosus* were recovered from the faeces. There was complete absence of *agglutinins to B. aertrycke* (two types), *B. paratyphosus* A and B, *B. typhosus*, and *B. abortus*. The serological investigations were conducted at the Royal Infirmary, Sunderland, on the tenth and twentieth days of illness.

Summary.

The pyrexia resembled that of typhoid fever, and on one occasion the temperature was higher in the morning than in the evening; the pulse was relatively slow, compared with the temperature. The fall in temperature and blood pressure was followed by pleurisy and pericarditis, and the general condition became worse. The brunt of the attack was borne by the heart and lungs, resembling in this some of the published *cases of psittacosis*. There is a strong suspicion that the illness may have been conveyed by a human carrier. I have reason to believe that if the agglutination tests were more generally adopted there would be fewer cases recorded as *psittacosis*.

PROTECTION AFFORDED BY SHORT INFRA-RED AND RED RAYS TO A LETHAL DOSE OF STAPHYLOCOCCUS.

ONE of us (A. E.) carried out a series of experiments, reported in the *British Medical Journal* (August 17th, 1929, p. 293), which showed that a preliminary *irradiation* of shaved rabbits with *artificial sunlight* increased their resistance to an intravenous injection of staphylococcus. A lamp was used which gave infra-red, luminous, and ultra-violet rays up to 2,850 A.U in amounts closely matching those of sunlight, and an intensity was used which did not produce severe erythema. A dose of staphylococcus was injected which proved constantly lethal to normal rabbits weighing about 2 kilograms. A fan was kept running so as to prevent any overheating of the irradiated animals during their preliminary exposure to light, which lasted forty-eight hours. The control animals all died within twenty-four hours. The irradiated animals survived for an average time of 7.43 days. One or two of these did not die.

We have carried out another series of experiments, exposing the animals to the light and heat of a gas fire. "Beam" radiant fuel was used in the fires, because this gives a greater amount of short infra-red rays, which penetrate the epidermis and cause an increased transudation of water in the skin. The heat from this type of fuel is more comfortable than the duller red heat, containing a larger proportion of longer and non-penetrating *infra-red* rays given off from the *ordinary* gas fire. These rays cause a dry, unpleasant feeling of heat in the skin exposed to them. The rabbits chosen were of about 2 kilograms in weight, shaved on both sides, and exposed in a wire cage to the cross-fire of two gas fires, one being placed

on each side of the cage. A fan was kept running so as to keep the rabbits cool. Their body temperature was not allowed to rise more than two or three degrees Fahrenheit. One or two animals did not change their position, and in these there were signs of a local severe erythema; but in most of the animals the erythema production was not significant. The dose of staphylococcus culture injected in each rabbit was 0.6 c.cm.; this dose proved lethal to all the non-irradiated control animals in the average time of 1.2 days. Protection was afforded by "beam" gas-fire radiation, but dark heat radiation of unshaved rabbits did not appear to have any protective power.

Total number of rabbits exposed to "beam" radiant gas fires...	10
Average weight in grams	1,924
Number of animals still alive	2
Number of animals which died	8
Average number of days alive after infection ...	5
Total number of control rabbits	9
Average weight in grams	2 276
Average number of days alive after infection ..	1.2
Total number of rabbits exposed to dark heat ..	4
Average weight in grams	2,340
Average number of days alive after infection ...	1.2

We conclude, then, that the short infra-red rays and red rays have the power—by acting on the skin—of increasing resistance to a general staphylococcal infection.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

CALCUTTA BRANCH.

Keratomalacia in Adults.

A CLINICAL meeting of the Calcutta Branch was held on December 13th, 1929, in the Calcutta School of Tropical Medicine and Hygiene, when the president, Major-General G. TATE, I.M.S., was in the chair, and twenty members were present. Lieut.-Colonel E. W. O'G. KIRWAN, I.M.S., read a paper on adult keratomalacia in Bengal.

Lieut.-Colonel Kirwan pointed out that keratomalacia or xerophthalmia was seen daily in the out-patient department of the Calcutta Eye Infirmary; it constituted the commonest cause of blindness among children in Bengal. The disorder was a complex and systemic one, associated with marasmus, affections of the alimentary tract, and dietary deficiences, while corneal degeneration was its most characteristic feature. According to the textbooks keratomalacia did not occur in adults, only very isolated cases having been reported in Europe and America; this was due to the high standard of living in those continents, but in the East matters were very different. Pillet had recently reported undoubted cases among adults in China. In Bengal the disease certainly occurred among adults, and all stages could be seen from simple xerosis corneae with hemeralopia to necrosis corneae, which constituted keratomalacia.

In adults the disease was a non-inflammatory malady of the eyeball, the margins of the lids being generally pale and dry. There was practically always present a mild conjunctival discharge due to secondary organisms. The lid conjunctiva, as a rule, took no part in the process, unless the disease was of long duration, when it might assume a trachoma-like condition. In the conjunctiva of the fornices, especially that of the lower fornix, there were present characteristic changes—follicles and pigmentation—often resembling the condition of argyrosis conjunctivae. The discoloration was similar to that of the skin and mucosae seen in scurvy and Addison's disease. The conjunctiva of the eyeball showed xerosis in the form of islands or one continuous layer. In the cornea the disease took the form of xerotic plaques or of ulceration. Exfoliation of the epithelium allowed the entrance of staphylococci or pneumococci, which broke down the tissues. The lens of the eye might also become involved in long-standing cases. Hemeralopia was often a very marked symptom, but it was sometimes difficult to elucidate, since it was necessary to depend on patients' statements.

Certain general symptoms indicated that the disease was a generalized and systemic one, the eye symptoms being only a part. Fever was practically always present. The blood showed reduction in the haemoglobin and a normal red cell count; there was usually leucocytosis. Skin pigmentation was often marked, sometimes so much so that the skin appeared as if there was a deposit of bile in it. The surface of the skin was rough and dry, and often covered with large numbers of comedones. Hyperkeratosis and parakeratosis were usually present, and multiple small follicular abscesses might be seen. The hair was dry and easily fell out; the nails might be affected. Other mucous membranes might be involved, showing the same changes as occurred in the eye—namely, replacement of cylindrical by squamous epithelium; the mucosae of the mouth, nose, throat, and intestine were frequently implicated, and severe diarrhoea might occur. A non-gonorrhoeal urethral discharge was often present. Wright believed that the thyroid gland might be affected, and McCarrison that all the glands of internal secretion, with the exception of the suprarenals and pituitary, might be involved. The condition amounted to an extensive disease of the ectodermal coat of the body, caused by general under-nourishment and absence of certain vitamins, especially vitamin A. In mild form xerosis of the bulbar conjunctiva occurred and culminated in keratomalacia with total blindness.

In treatment, cleanliness and protection were the local essentials. Cod-liver oil was the best remedy, but should be administered cautiously in patients with diarrhoea; it might also be rubbed into the skin. Fresh milk and vegetables should be given freely. A mixture of the chlorides of calcium, sodium, and ammonium was useful, as also was fresh liver. The disease responded slowly to treatment, the prognosis being bad if both corneae were attacked before treatment had begun. The condition was preventable, but, like most of the health problems of Bengal, resolved itself into an economic and financial matter, rather than one for the medical practitioner.

At the conclusion of his paper, Colonel Kirwan showed six illustrative cases.

The first patient was an adult male coolie, on a good general diet, but involved in very severe physical work.

The second patient was a boy, aged 12, with diarrhoea and fever, the conjunctival epithelium having become converted into squamous epithelium.

The third patient was a man, aged 45, with hazy vision of only fifteen days' duration. He had had two months of night-blindness, however; the haemoglobin percentage was only 50, and the red cell count had fallen to 3,000,000 per c.mm. Here the diet had been very insufficient, and a strongly positive Wassermann reaction was present.

The fourth patient, a man aged 31, had, in the right eye, only perception of finger movements, and 50 per cent. diminution of vision in the left. The whole cornea in one eye was necrosed.

The fifth patient, a man aged 40, had had night-blindness for a year, and only retained perception of light in both eyes. The conjunctivae were of a mahogany colour, and there was sloughing right down to Descemet's membrane. The skin was dry, scaly, deeply pigmented, and covered with comedones.

The sixth patient was a woman with advanced disease, but her 6 months old baby was perfectly healthy. Her diet had been only rice and dal, with no fish or milk.

In the subsequent discussion General TATE inquired whether the disease attacked any particular type of patient, and whether it occurred in provinces other than Bengal. Major G. SHANKS, I.M.S., commented on the general systemic conditions which predisposed to secondary bacterial invasion of tissues. Wolbach's experiments had shown that in conditions of vitamin deficiency keratinized epithelium might replace the normal mucosa of the respiratory, alimentary, and urethral tracts, and the ocular conjunctiva. Lieut.-Colonel T. C. BOYD, I.M.S., asked whether Colonel Kirwan had tried treatment with endocrine products, and suggested the administration of thyroid gland. Dr. COLTMAN said that keratomalacia in children was especially associated with fat dyspepsia and coeliac disease. In such cases peptonized milk given for three weeks cured the condition. Dr. S. C. DUTT thought that hemeralopia and the skin changes were characteristic of the disease; in Calcutta it was confined to up-country patients, who lived chiefly on a diet of kesari and other

dals, and it did not attack the Bengali who took fish in his diet. It might end in optic atrophy. Dr. S. K. DAS, on the other hand, stated that he had seen instances of the disease in the children of well-to-do Bengali families; cases were often associated with diarrhoea.

In reply to questions, Colonel KIRWAN commented on cases with a urethral discharge which had been mistaken for gonorrhoea; Colonel R. E. Wright had found the administration of thyroid gland very useful in treatment, while liver feeding tended to cure the anaemia. The progress of hospital cases was usually very slow. True trachoma was very rare in Bengal, and seldom complicated the disease. He had not, so far, studied the blood calcium content in connexion with keratomalacia.

Reports of Societies.

RADIUM IN GYNAECOLOGY.

THE Sections of Obstetrics and Gynaecology and of Electro-Therapeutics of the Royal Society of Medicine combined on February 21st for a discussion on the position of radium in the treatment of gynaecological conditions. Mr. ARTHUR E. GILES, president of the first-named Section, was in the chair.

Mr. MALCOLM DONALDSON said that knowledge of the action of radium was still imperfect, but one outstanding fact was that quickly growing cells in an active state of metabolism were far more affected by radiation than more stable cells. This direct action of the rays on the cells was the basis of all radiotherapy. The question of radiosensitivity was abstruse; certain tumours disappeared very rapidly, others with difficulty. Upon what the difference in radiosensitivity depended, whether on the blood supply or the histological structure, was not yet determined, nor was it known whether the action of radium was purely direct or was combined with an indirect action brought about by the surrounding tissues. In view of the imperfect knowledge of the fundamental facts involved it was not surprising that most techniques were empirical. Although it was possible to define dosage as the weight of radium element multiplied by the duration of exposure, yet in practice this gave very little information because the intensity of the radiation fell off very rapidly the further the radium was from the individual cell. It was obvious that the same amount of energy would be received by a cell if 100 mg. were used for one hour or 1 mg. for 100 hours; therefore merely to state that the patient was treated with so many milligram-hours did not convey exactly what treatment had been given. Even when the several factors in the dosage had been stated, the problem of how the dosage should be made up was not solved. From clinical observation it appeared that for certain types of growth, particularly slow-growing tumours, it was better to apply a small intensity for a long time than a large intensity for a short time. The radiological treatment of carcinoma of the cervix had been chiefly conducted by radium applied per vaginam. The problem for gynaecologists was how to destroy the growing edge of the tumour in the deeper parts of the pelvis, and the metastases in the glands. When a growth had spread beyond a very limited area no application of radium by the vagina alone could possibly cure the patient. For this reason x rays were now employed in many centres in the hope of increasing the effective range of the radium. Carcinoma of the vulva required a little more specialized technique. For the primary focus needles of an intensity not exceeding 0.6 mg. per cm. length should be used, placed at least 15 mm. apart, and the radium left *in situ* from ten to twenty days, but there was not yet sufficient evidence to make the procedure more exact as to length of time. The glands were a much more difficult problem, but the columbia wax method of placing the radium over the whole inguinal area at a distance from the skin of 1 cm. was probably the most efficient at present available. There was very little to be said concerning the radiological treatment of the body of the uterus, since most of such cases could be efficiently treated by means of hysterectomy. When hysterectomy was contraindicated, it would appear that a combination of x rays followed by 50 mg. of radium left in the cavity of the body from ten to fourteen days was of very great value. Rapidly growing tumours such as chorion epithelioma should be treated first by x rays, and then, if the primary focus was not very extensive, radium should be used in addition.

Dr. J. E. A. LYNHAM, speaking from the electro-therapeutical side, said that while the gynaecologist had become established and his position well defined, the radiologist had not yet fully evolved. Coming generations of medical men would be amazed to find that anyone should have been permitted to cover the enormous range expected from the present-day radiologist. In the course of time, as radiology came into its own, the subject would be subdivided, and there would be specialization in particular branches. It did not seem probable that the radiologist would proceed to perform operations for the surgical use of radium; it was more likely that the surgeon of the future would devote part of his training to a serious study of the tissue changes brought about by radiation. Particularly in regard to malignant disease, the consideration and treatment of a patient was really at its best when entirely in the hands of one man. At present there was a tendency to dissociation, and in some institutions the radium department was being separated from the radiotherapeutic department. The surgeon and gynaecologist had their parts to play in the application of radium, and they would of necessity work in co-operation with those directing radiotherapeutics. Proceeding to speak of experiences with radium in gynaecology, Dr. Lynham said that in the treatment of cancer two separate things had always to be borne in mind—namely, the effect of the radiations on the malignant cells, and the effect on the stroma and adjoining tissues. In sarcoma, he believed, the more important action was on the cells of the tumour; in cancer, on the other hand, the ideal radiation was one which would inhibit or destroy the malignant cells, not only without injury to the adjoining tissues, but in such a way as actually to assist them in their efforts to overcome the invading cells of the growth. Many failures in early days could be attributed to a dosage of too great intensity. It was generally accepted that the shorter wave-lengths of the gamma rays had a more inhibiting action on the cancer cells than the x rays, while there was more effect on the stroma as the result of x rays than as the result of radium. In the treatment of cancer, therefore, greater success could be expected from the judicious combination of x rays and radium than from either agent alone. He had been more successful where radium was first used for its local effect and x-ray treatment begun before the influence of the radium had subsided. Dr. Lynham sketched the early work at the Radium Institute in London, with which he himself had been associated, and also the development of the Stockholm, Paris, and Baltimore techniques. In the history of the treatment of malignant disease of the cervix and vagina, the enthusiasm generated by early improvement had been followed by disappointment as the disease reappeared and extended. In cases where the glands were not palpably enlarged it ought to be possible to do a great deal by means of heavily screened high-voltage x rays, and this should be taken up as a serious adjunct to treatment by radium. The fact must not be overlooked that radium was so far a local treatment for local manifestations of cancer, and cancer was a progressive disease, tending to invade new structures. Whether using radium or x rays some method of prophylactic irradiation should be employed, the doses for which need not be heavy or cause any serious tissue damage. Even when the tumour could not be made to disappear, its rate of growth might be slowed and the life of the patient prolonged. One aspect of treatment did not always receive the attention it deserved—namely, the preparation of the patient before radiation methods were applied. The removal of septic foci, and the use of vaccines, tonics, ultra-violet radiation, and hypodermic or intramuscular medication might be of assistance. It was to be hoped that enthusiasm for one particular method would not prevent systematic exhaustive trials of other methods. The whole subject was merely at its beginnings; the possibilities were immense, the potentialities as yet

largely unexplored. When the efforts for the cure of cancer had reached a greater measure of success, it would be realized that much of the credit must go to the gynaecologist; if only the spirit of consultation and mutual correction which prevailed in such a discussion as the present could be carried over into the hospitals success would be expedited.

Mr. STANLEY DODD dealt with radium in the treatment of non-malignant disorders of the uterus. The indications for treatment were cases in which menstruation was regular but profuse, with no abnormal physical signs, and no suspicion of malignant disease, also menorrhagia associated with metritis and climacteric bleeding, and menorrhagia associated with general diseases, such as tuberculosis, where the monthly loss was greater than the patient could afford. It was also indicated in intractable dysmenorrhoea, not alleviated by drugs or modern endocrine or other treatment; in fibroids of the uterus (he had only had occasion to use radium in two cases of fibroids in young patients who were unsuitable for operation, and both were relieved); and in chronic cervicitis, though in this last condition, in which radium had been tried by needling, the results had been disappointing. It was the speaker's clinical experience that with proper screening—he mentioned a screen of 1 mm. platinum—radium could be kept inside the uterus for twenty-four hours without leading to any unfortunate sequels. He gave records of 61 cases in which radium had been used in non-malignant disorders, and added some remarks about carcinoma. It was fair to say that radium would eradicate primary growth in nearly all cases. The problem was to clear up metastases, and secondary deposits in the glands were more difficult to deal with than was the primary growth. The rational course seemed to be to extirpate the glands. To use the vaginal application of radium only was to condemn 40 per cent. of cases to recurrence. It was necessary to decide both how and when to deal with the lymphatic system, because it had to be remembered that the lymphatic system was the last line of defence against carcinomatous invasion. Mr. Dodd described in detail his own special technique for radium application.

Dr. RUSSELL REYNOLDS remarked that radium treatment could not be dissociated from deep *x*-ray therapy. He had been struck with the importance of using a split-dose technique. This seemed a common-sense point of view to take, because if one was using a very large dose of deep *x* rays or radium it involved a lowering of the resistance of the patient as well as of the tumour. If the dose was split the patient's resistance was better maintained. He thought, therefore, that the use of *x* rays in conjunction with radium was very important. He agreed with the use of radium first of all for local action, the treatment being completed by *x*-ray therapy.

Dr. W. M. LEVITT thought there was general agreement about the value of combined treatment, but a point not usually sufficiently appreciated was that the technique of *x* rays might be considered as complementary to the technique of the application of radium. *X* rays were applied externally, and the zone of maximum intensity tended to be at the periphery of the growth. Radium was applied locally, and therefore its zone of maximum intensity was at the centre. The two methods from the point of view of technique, therefore, could be regarded as complementary. With *x* rays recurrences were almost invariably local; with radium rarely. There was still another and more fundamental point to which no reference had been made—namely, that the character of the stimulus of radium was essentially different from that of *x* rays. Radium was applied continuously perhaps for several days; *x* rays were applied in split doses. Even though the action might be identical, the results of a continuous and of an intermittent physical stimulus were entirely different. Intermittent pressure on the toe, for example, would give rise to a corn, but continuous pressure would give rise to necrosis. The fact that the type of injury to the tissues might be different was supported by the evidence that it was possible to combine a full dose of radium with a full dose of *x* rays without producing a burn. On that ground he suggested a combination of the two agents. It might also be found that the application of *x* rays followed by radium gave very different results from the application of radium followed by *x* rays. His own view was that it was preferable to precede radium with *x* rays.

Dr. S. GILBERT SCOTT said that one was apt to think that the cure of malignant disease was bound up with the disappearance of the tumour. The primary growth in quite a number of cases could be made to disappear by the surgeon, the diathermist, or the radiologist, but unless the problem of the secondaries was also tackled there was no justification for talking of cure for cancer. In very few cases did the primary disease kill the patient, nor was the patient killed by secondary growths in the groin or axilla. Patients most commonly died with secondary growths in the liver, spleen, and thorax, and until some satisfactory method could be devised of preventing metastases from developing in these regions the mere disappearance of the primary growth did not justify any claims to cure.

Dr. J. M. WYATT referred to the treatment of pruritus of the vulva. In many cases where *x* rays seemed to have no effect small doses of radium had brought extraordinarily marked relief, sometimes lasting for two years. Mr. M. H. OLDERSHAW thought one of the reasons for partial failure after the introduction of radium into the uterus in non-malignant conditions was that the radium was not arranged advantageously so as to affect all parts of the endometrium. He had taken care in the case of a large uterus to split the dose of radium up so as to obtain as uniform an effect as possible. Mr. DUNCAN FITZWILLIAMS was interested in the statement that the primary tumour could be made to disappear, but that when it came to the glands the problem was wholly different. In another branch of surgery a carcinoma of the tongue could readily be made to disappear, but when it came to dealing with glands in the neck, in spite of radium application—surface, interstitial, or other—block dissection was the sheet anchor. Mr. Dodd screened his radium with 1 mm. of platinum. That was the largest screening he knew, and he felt that there was a field for experiment with different screenages. A screen of 0.5 mm. platinum had been accepted, but he was quite sure it was wrong.

Dr. PATTERSON gave particulars of an investigation which had been proceeding at St. Bartholomew's Hospital to endeavour to ascertain the prognosis as regards radium treatment according to the type of growth revealed by the microscope. The figures so far ascertained, however, were not suitable as a basis for discussion, because the earlier cases had been treated by different procedures in respect of dosage and length of time. It was proposed to await five-year results of cases which had all been treated on the same basis. As far as the work had gone, however, it showed that the more immature the cell growth the better was the prognosis from the point of view of radium treatment. Dr. GILBERT I. STRACHAN said that from the point of view of saving the life of the patient, cure of cancer was scarcely yet in sight, but from the point of view of relief of symptoms in almost 100 per cent. of cases the primary lesion would clear up, with relief of bleeding. In a certain small proportion of cases, however, there was no relief, and no actual amelioration of pelvic pain, and research on these resistant cases was desirable. The matter of fistula formation was another important point. Fistula occurred in a certain proportion of cases after radium just as after any other kind of treatment, or after no treatment. Dame LOUISE MCILROY commented on the value of co-operation between the radiologist and the gynaecologist, and eulogized the organization of Regaud's clinic in Paris. She agreed that the main question was one of hours rather than of the amount of radium. The present discussion had largely turned on radium *versus x* rays; she agreed that *x* rays affected the ovary, and radium the endometrium.

The CHAIRMAN (Mr. Arthur Giles) said that one lesson which had emerged from the discussion was that workers must not pin their faith exclusively to one method of treatment. Radiation must not be regarded as taking the place of surgery, but as supplementing it. With regard to induction of the menopause there was a class of case in which the object was primarily to arrest haemorrhage, not to bring about the menopause or produce atrophy of the ovaries; in such a case he believed radium more

valuable than *x* rays, because of its more limited scale of action.

The openers briefly replied, Dr. LYNHAM taking up the chairman's last point by saying that a number of young women had been treated at the Radium Institute for uterine bleeding. In no case had he known the artificial menopause which ensued to last longer than nine months. This corresponded to the gestation period, and supported the view that the superficial follicles were more susceptible, and the deeper ones less susceptible, to treatment.

APHONIA.

AT a meeting of the Section of Laryngology of the Royal Society of Medicine, on February 7th, under the presidency of Dr. DAN MCKENZIE, Miss E. C. MACLEOD gave a demonstration of an apparatus for the treatment of functional aphonia and similar disorders, basing her remarks on the treatment of seventy-five cases. In true aphonia, she said, there was little or no approximation of the vocal cords when phonation was attempted; in hyperphonia not only were the cords forcibly brought together, but the ventricular bands were also approximated, so that phonation was almost impossible; if audible at all, the voice was high-pitched, hard, or very hoarse. The most satisfactory treatment for the first group was the application of the faradic current by means of the synchronized stimulator, accompanied by strong suggestion or persuasion. For the second gentle phonation could be induced by vocal and muscular exercises, which relaxed the existing tension. The synchronized stimulator was contraindicated in these cases. A second treatment was usually unnecessary.

Mr. V. E. NEGUS thought that treatment of speech defect ought to be the work of a specialist. At King's College Hospital the orthophonic department worked in close collaboration with the laryngological department. During a discussion of the method Miss MACLEOD said she preferred gentle phonation to that which resulted from muscular pressure applied to close the cords.

Mr. H. BELL TAWSE showed a patient with a growth on the right side of the larynx in whom aphonia had been followed by hoarseness. The Wassermann test was negative. In discussing the patient's claim to a pension on account of having been gassed in France, several speakers thought it unlikely that the claim would be allowed, as the symptoms had matured about thirteen years later. Others thought that this delay should not invalidate the claim. Mr. POPPER advised a provocative injection of novarsenobillon before absence of syphilis was accepted.

The PRESIDENT showed a case of unilateral fixation of the larynx, apparently congenital. Breast-feeding had been impossible on account of dyspnoea. The patient was now 21 years of age. Mr. O'MALLEY thought there must have been some trauma at birth. In this case there was a thickening similar to that in healed laryngo-fissure.

Mr. O. POPPER showed a case of what he regarded to be a clinically primary tuberculosis of the larynx, in which the diagnosis lay between epithelioma and tubercle. Dr. JOBSON HORNE thought the word "primary" ought to be omitted for lack of other authentic evidence.

Mr. NORMAN PATTERSON showed a patient, aged 66, with nasal sinus disease involving the orbit. Three years ago the right eye swelled and pain was felt above it; but there was no headache or nasal catarrh. Polypi were removed from the right side of the nose, which discharged on being probed later, and the eye swelling subsided. Two weeks later a sinus developed on the inner side of the eye, accompanied by a profuse blood-stained discharge. There was also a discharge from the right side of the nose, which passed down the throat. When three stitches had been inserted, following an external operation, the discharge ceased for a week; subsequently, however, the swelling increased, and the eye was displaced forwards, outwards, and downwards. Double vision ensued, with persistence of pain in the supra-orbital region. A fluctuating swelling was found extending from the nose to the outer limit of the orbit. The skin could be easily moved over the swelling, but it was inflamed in the region of the sinus. A hard, rounded, smooth swelling projected from the lateral wall, and there was some polypoid tissue on the left side. It was remarkable that the displaced eye had vision 6/24.

Mr. MUSGRAVE WOODMAN spoke of a patient whose right eye extruded; sight and temperature were normal, and he was free from pain and symptoms. The *x* rays revealed nothing; no operation was performed, and the patient returned home apparently well. A month later he came with exactly the same condition, and on this occasion *x* rays showed suggestion of a swelling in the ethmoidal region. The ethmoidal cells at the back of the eye were found to be full of thin, clear mucus. When this had been drained into the nose and the outer wound closed up, the eye returned to its normal position; its movements were re-established, and sight was unimpaired.

Mr. RITCHIE RODGER also described a case where the patient had diplopia and slight swelling in the ethmoidal region. An external operation revealed a greatly enlarged frontal sinus, the healed cavity being filled with a material of a glue-like consistency.

Mr. NEGUS illustrated by lantern slide a case in which a non-opaque foreign body had lodged in the left lower lobe bronchus. While playing with a carrot, an infant of 1 year and 10 months inhaled a portion. A slight cough ensued, but definite signs in the chest could not be detected until the following day, when there was almost complete loss of air entry in the left lower lobe and impaired air entry in the left upper lobe. Bronchoscopy revealed a piece of carrot, which was removed from the trachea; another was removed from the left lower lobe bronchus. The child was well the next day.

Mr. M. VLASTO showed a case with associated paresis of the internal tensors and abductors of the vocal cords, where there was combined bulbar paralysis and progressive muscular atrophy. The patient had dysphagia when taking solid food. The paresis developed very slowly. In addition to the bilateral abductor weakness in the larynx there was typical bowing of the vocal cord on the right side, due to paresis of the thyro-arytenoideus muscles. Dr. FEILING considered that the bulbar symptoms were due to degeneration of the hypoglossal nucleus and the nucleus ambiguus in the medulla.

Mr. O. POPPER exhibited a silvered operating reflector, which he said had a reflecting capacity superior to that of the all-metal sterilizable type. It was compact and cheap.

CYCLICAL CHANGES IN THE ENDOMETRIUM.

AT a meeting of the Manchester Pathological Society on February 12th, Professor JOHN H. TEACHER gave an address entitled "The endometrium and decidua." Photographs of low magnifications were shown to demonstrate the structure of the normal membrane and the great increase in its thickness during the menstrual cycle, in the formation of the decidua, and under certain pathological conditions. Attention was particularly directed to the decidual group of slides; the relations of the structural changes to menstruation, ovulation, and fertilization were discussed. Professor Teacher disagreed with the current views on the association of these functions, and suggested that ovulation was not a regular but an occasional phenomenon, that menstruation did occur in the absence of ovulation, and that the pre-menstrual proliferation of the endometrium might possibly in these circumstances be omitted. These views were founded partly on the lecturer's study many years ago of the histories of young human ova, and on the recent observations of Professor G. W. Corner on monkeys. According to this theory the cyclical changes in the endometrium would develop only when ovulation and the formation of a corpus luteum also occurred. The still greater proliferation of glands and the cellular changes in the direction of decidua, which were at one time described as endometritis glandularis hyperplastica, would be associated with fertilization of an ovum which might or might not become implanted. Lantern slides at higher magnification were then shown and their interpretation was discussed in the light of this theory.

LIVERPOOL MEDICAL INSTITUTION.

AT a meeting of the Liverpool Medical Institution on Thursday, February 6th, Mr. T. GUTHRIE read a short paper on foreign bodies in the air passages. He said that during a period of twenty-three years he had treated eighteen cases of foreign body in the trachea and bronchi, besides a few others in the larynx. He gave an account of a number of these cases, showing lantern slides to illustrate the various types of foreign bodies and the problems involved in their removal. In reference to the diagnosis of foreign bodies in the bronchi, stress was laid on the importance of such symptoms and signs as the "asthmatoid wheeze," and the position and degree of respiratory movement of the diaphragm, as observed on *x*-ray examination. Particular attention was drawn to the irritating effects of foreign bodies of vegetable origin, especially the "arachidic bronchitis" described by Chevalier Jackson as due to the inhalation of peanuts. The assistance of an expert anaesthetist was most important. Rectal ether anaesthesia, supplemented by the inhalation of a small quantity of chloroform, had proved very satisfactory in one or two of the cases.

Mr. H. F. WOOLFENDEN described the type of case diagnosed as chronic appendicitis, or appendix dyspepsia, for want of a more exact diagnosis, and said that his experience was that there was a high return of this type of case after simple appendicectomy. Moreover, the slight changes found in the appendix were often not sufficient to account for the symptoms. It was noticeable how frequently a very mobile caecum and ascending colon were found in this type of case, and it was determined to try the effects of fixing the caecum and ascending colon as well as removing the appendix. Acknowledgement to Waugh for his pioneer work on this subject was made, and to the paper by Carslaw. During the past four years a small series of cases had been treated, and 49 of them were traced; 29 patients were completely cured, 6 were cured except for persistent constipation, 1 complained only of pain in the scar, 11 were relieved, and there were 2 failures. Of the cases operated on, 5 patients had previously had their appendix removed unsuccessfully, and they were all cured or very much relieved by the colopexy. On analysing the condition of the appendix in the other cases, it was found to be normal in 14, kinked in 5, to contain concretions in 7; 9 showed fibrosis, 3 were bound down, and 2 showed slight congestion. In the 14 cases where the appendix was normal cure or great relief followed the operation. The theories as to the cause of the symptoms were briefly reviewed.

In the discussion which followed, Mr. FRANK JEANS said he did not as a rule advocate fixation of organs originally mobile. But he believed in the genuineness of the cures in Mr. Woolfenden's cases because the psychological element could be disregarded. Neurotic patients were not cured by operation; they merely complained of the operation instead of the original disease.

UTERINE MALIGNANCY.

AT the last meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland, the president, Professor A. H. DAVIDSON, showed specimens and lantern slides of two malignant growths in the uterus.

Case 1.—A woman, aged 58, had been married for twenty-seven years, but had had no children. The menopause had occurred nine years ago; there had been slight leucorrhoea during the past twelve months, slight irregular bleeding during the past four months, and a sharp haemorrhage one month ago. She had lost weight. The vaginal cervix appeared normal, but the supravaginal cervix was greatly enlarged; the body of the uterus was difficult to feel, but seemed to be enlarged. Passage of a sound into the cervical canal revealed a breaking-down cavity, and there was a blood-stained fetid discharge issuing from the uterine cavity. The uterus and cervix were mobile, and there was no extension into the parametria, bladder, or rectum. An endocervical cancer was diagnosed, and Wertheim's hysterectomy was performed. There was difficulty in separating the lower part of the rectum from the back of the cervix, but the adhesion did not appear to be malignant. At one place on the anterior uterine wall the growth had almost eaten its way through. A gauze drain was led out through the vagina.

Pathological examination revealed the condition as being an endocervical cancer with extension to the body of the uterus. Sections showed masses of squamous cells growing in a malignant formation, and at other places masses of cancer cells with the formation of an adenocarcinoma; it was probably an example of metaplasia.

Case 2.—A woman, aged 52, had been married for thirty years. She had complained of purulent vaginal discharge for the past six or eight months and frequency of micturition. She had had an abortion, with instrumental intervention, twenty-nine years ago, followed by atresia of the cervical canal and retention of menstrual products. In order to overcome this difficulty double oophorectomy was performed; since then the patient had never menstruated. The vulva and vagina were atrophic, especially in the upper part, and there was a pinhole opening in the vaginal vault, through which purulent material was issuing. The body of the uterus was enlarged to the size of a grape fruit, and was irregular. No cervix could be seen. A diagnosis was made of myomatous uterus with pyometria, and total hysterectomy was performed.

The pathological report stated that sections of the tumour showed that it was a large myoma, with advanced hyaline degeneration; the nuclei of the muscle fibres stained intensely, and revealed a tendency to proliferation, many mitotic figures being seen. This deep staining and proliferation was also seen in the muscle wall of the uterus. The cell proliferation seemed to be continuous with the stroma. There were a few areas of interstitial haemorrhage and the condition suggested a sarcomatous change originating in a myoma which had developed in the absence of the ovaries.

Dr. BETHEL SOLOMONS said that the greatest interest to him lay in the fact that malignant disease followed atresia of the cervix. This bore out the contention which Graves had emphasized and illustrated in his excellent paper at the British Congress of Gynaecology two and a half years ago, that one of the very common causes of malignant disease was insufficient drainage. The specimen showed clearly that myoma uteri could occur when the ovaries were absent.

Dr. GIBBON FITZGIBBON suggested that the tumour in the first case might have been a primary fibro-sarcoma. He mentioned a similar case which he had shown at the Academy some years previously, in which the opinion was that the whole tumour was a fibro-sarcoma, some parts of the tumour being more sarcomatous than others.

The PRESIDENT, replying, said that myomata might have been present at the time of the first operation, but as the patient was then only 22 years old he thought it was unlikely that they were. Sections taken from the centre of the tumour showed definite myomatous tissue. The appearance of the tumour was that of an ordinary interstitial myoma which was becoming submucous; he had not suspected malignancy until he had received the pathological report.

Uterine Haemorrhage of Doubtful Etiology.

Dr. J. F. CUNNINGHAM showed a uterus and ovary, and read notes on a case of long-standing frequent and profuse uterine haemorrhage in a woman aged 30.

The patient had been curetted and treated with drugs and glandular extracts without any beneficial result. When first seen by Dr. Cunningham she complained of haemorrhage, backache, and weakness, looked very anaemic, and her haemoglobin was only 51 per cent. Examination under anaesthesia revealed a slight enlargement of the uterus, and a scraping of the endometrium showed hyperplasia. Treatment for the anaemia was prescribed, and the patient returned four months later looking and feeling better, but the uterine bleeding had in no way altered. She was then given radium treatment, with the object of producing a temporary artificial menopause; this was followed for a month by a continuous slight uterine bleeding. One month later she menstruated heavily for ten days; she then had a period of amenorrhoea, which lasted for two and a half months, followed by a heavy menstruation, which lasted for seven days. After an interval of six weeks there ensued severe haemorrhage, which continued for three weeks. Eleven days later the abdomen was opened, and the uterus and adnexa appeared anaemic and oedematous. The uterus was slightly enlarged. The left ovary was small, convoluted, and neither cysts nor follicles were visible. The right ovary was enlarged, and contained what appeared to be three corpora lutea, one of them being cystic. The uterus and right ovary were removed.

The pathological report by Dr. McGrath stated that the uterus was slightly enlarged, the endometrium being thicker than normal; it was irregular and showed projections. In the middle layer a few acini showed cystic dilatation, but no cells were present in these cystic spaces. There was slight oedema, and some of the acini were situated deep in the muscle. The ovary contained one corpus luteum cyst and two fully developed corpora lutea. There was also a follicle cyst present, but only about half the normal ovarian tissue, and Graafian follicles were extremely scanty. There was no evidence of inflammation.

Dr. Cunningham said that the points of interest in this case were the cause of the bleeding and the classification of the condition. Before the treatment with radium the

symptoms and the microscopic appearance of the endometrium corresponded with what had been described as the epimenorrhoeal type of uterine haemorrhage. After the radium had been applied the periodicity of the menses changed, and resembled more the type found in metropathia haemorrhagica. The pathological report on the specimen showed that the endometrium was of the type described in that condition. The right ovary, however, contained corpora lutea (which were not found in metropathia haemorrhagica) of the type found in metrorrhagia or epimenorrhagia. Hysterectomy was performed in preference to ovarian sterilization by *x* rays.

The PRESIDENT thought Dr. Cunningham might have tried either removal or resection of the ovary which was at fault in this case. He did not think it was such a serious matter to subject a patient to two laparotomies if the object was to save the uterus. Dr. J. LAIT said that the endometrium was hyperplastic, with far too many glands, and the stroma was fibrous. The obvious characteristic in this type of case was the presence of the glands, and he personally always reported the condition as chronic cystic endometritis. He thought the condition was not recognized under a separate heading, and was generally found in elderly women with persistent haemorrhage. Dr. J. S. QUIN mentioned a case, which had been reported by Dr. Pollock, of acute dysmenorrhoea which had not been relieved by curetting, but had been relieved by radium treatment.

Dr. BETHEL SOLOMONS regretted that Dr. Lait had described the case as cystic endometritis. It seemed to him that the uterine condition was secondary, and that the main cause of the haemorrhage was persistence of the corpora lutea; this seemed to be clearly shown in the specimen. Oöphorectomy might have cured, but it could not be risked. Dr. D. J. CANNON considered that the case belonged to the category of functional uterine haemorrhages. The history of the case before radium treatment was one of hyperovarian activity, and he thought that the insertion of radium had converted it into hypo-ovarian activity. Dr. R. M. CORBET drew attention to the fact that the uterus was very large and fibrous; he supposed that its present condition was due to the radium treatment. Dr. T. M. HEALY said that apparently only one ovary was unhealthy; he did not think the case could be considered one of typical ovarian bleeding.

Dr. CUNNINGHAM, replying, said that he did not feel he could take the risk of only removing the ovary, particularly as he was not absolutely certain that it was the ovary which was at fault. He did not regard the case as one of endometritis, because there were no signs of inflammation in the endometrium, no plasma cells, and the myometrium was quite normal. He did not think that the radium treatment had had any influence whatsoever on the uterus itself. There were no symptoms of hyperthyroidism of any kind. The patient had been treated with thyroid extract and with ovarian extract without any result.

Acute Uterine Inversion.

Dr. J. S. QUIN read a paper on acute inversion of the uterus. He reported the case of a woman, aged 30, who had had two children previously. At the birth of the third child there had been precipitate delivery, with delay in the expulsion of the placenta. The after-pains were somewhat severe, and on the fourth day after delivery prolapse suddenly occurred. Reposition was effected under anaesthesia, and was followed by uneventful recovery.

The PRESIDENT said that he had only seen one case of complete inversion of the uterus; this occurred in a patient who was very toxaemic and had had an accidental haemorrhage. The patient died from an attempt to return the uterus to its normal position. In the case reported by Dr. Quin the inversion had not occurred for some days, and the President wondered if it was possible that the inversion had started during the third stage of labour, being originally a partial inversion, which later became complete. Dr. BETHEL SOLOMONS remarked that inversion of the uterus was nearly unknown in Ireland; he regarded this as a tribute to Irish obstetrics. He had not seen a case of acute inversion for twenty-one years; in that instance he replaced the uterus, but inversion occurred, so he replaced it again and plugged the uterus. The plug gave the uterus something to contract on, and complete recovery ensued. Dr. GIBBON FITZGIBBON agreed that acute inversion of the uterus was extremely rare. He mentioned a case in the Rotunda Hospital in which the patient was nearly moribund from ante-partum haemorrhage, but in this instance the uterus went back easily. He also cited another case in which inversion of the uterus could be felt; by lateral massage of the uterus the condition was corrected. He had also seen a case in which the fundus of the uterus appeared above the vulva; the organ was replaced, plugged, and there was no recurrence.

Dr. J. F. CUNNINGHAM referred to a case in which the fundus of the uterus was visible at the vulva and the placenta had been expelled; he thought the most important thing was to give the patient an anaesthetic. In his case, under anaesthesia, the uterus would not at first go back, but later the cervix relaxed and the uterus was replaced. He did not think it was often necessary to plug the uterus, and believed that the less foreign material which was put into the uterus after confinement the better. In most cases he regarded the giving of ergot as sufficient. Dr. HOPE TRANT reported a case of inversion of the uterus which she had seen in South Africa, in which the patient was not suffering much from shock, and there was no haemorrhage. She had replaced the uterus, and the patient remained well. Dr. D. O'SULLIVAN mentioned a case in which inversion occurred in the third stage of labour in an effort to expel the placenta. When he saw the patient she was moribund, and died shortly afterwards. Dr. O'DONEL BROWNE thought that in patients suffering from profound shock no manipulation should be undertaken which would in any way increase the shock. Traction on the fundus might control the bleeding temporarily till aseptic measures could be taken for the reposition of the uterus. Dr. G. TIERNEY said that it had been stated by Braun that complete inversion of the uterus occurred once in 250,000 cases. In Dublin it occurred once in 190,000 consecutive labours. Zangemeister reported that 23 per cent. of these patients died if reposition was performed immediately, but none died if time was taken before this measure was attempted. Dr. R. M. CORBET believed that in some cases in which death was stated as being due to immediate replacement it was really attributable to profuse haemorrhage.

Dr. QUIN, replying, suggested that one reason for the rarity of cases of complete inversion of the uterus was that very many of them were not reported. He believed that the benefits of giving saline injections and treatment by blood transfusion largely outweighed the reaction which they caused. According to the literature, haemorrhage did not seem to occur in the majority of cases. Inversion was much more likely in uteri which were not completely atonic than in those which were. After replacement the best treatment was to pack the uterus with gauze.

MAXILLARY SINUSITIS.

AT a meeting of the Brighton and Sussex Medico-Chirurgical Society on February 6th, with the president, Dr. W. BARRINGTON PROWSE, in the chair, Mr. HAROLD DOWNER read a paper entitled "Maxillary sinusitis." He emphasized the necessity of having a thorough understanding of the morphology and function of the nose and antrum in order to conduct treatment rationally, and dealt with the pathology of the disease, with particular reference to the researches of Hajek, Onodi, Studer, and others. Maxillary sinusitis in children was discussed, and mention was made of the establishment by Graham Brown of the connexion between this complaint and bronchiectasis. Mr. Downer advocated conservative treatment in dealing with the acute antrum, and added that antral puncture should only be employed in cases which did not respond to physiological rest, posture, and local treatment. The intranasal route furnished the operation of choice, and gave the best results. Radical methods were practically unnecessary in uncomplicated sinusitis, and should be reserved for cases due to such causes as foreign bodies and impacted dental roots. Radiograms of a few cases were shown, and the results of treatment were described.

Reviews.

ARTHROPLASTY.

IN *The Mobilization of Ankylosed Joints by Arthroplasty*[1] Drs. RUSSELL and ANDREW MACAUSLAND give us the benefit of their very large experience of operations designed to replace a stiff joint by a factitious movable one. Since the days of Ollier of Lyons, whose pioneer work led more to excision than arthroplasty, and who, we may remark in passing, is hardly mentioned in this book, Murphy of Chicago must be looked upon as the real father of arthroplastic measures for the relief of ankylosis, especially of the hip- and knee-joints; but he had few immediate followers, and it was due to the results obtained from the methods of Putti of Bologna after the war that a revival of interest in the subject took place. Besides Putti, Payr, Kirschner, Willis Campbell, Baer, and others worked at improving technique and studied the practical difficulties of various operative procedures, so that these operations, on certain joints and in selected cases, may now be considered as well-established methods of treatment, capable of relieving sufferers from grave disabilities. Nevertheless, let no one suppose that such operations are to be lightly undertaken by the surgeon or submitted to by the patient unless they have both well weighed the pros and cons, and the latter has made up his mind to bear a great deal of inconvenience and some pain with fortitude and a determination to make the result a success. For in the after-treatment of these cases active movements count for very much more than massage or passive movements, and the mental stamina and will to succeed of the patient is at least as important as his blood count.

The first part of the book is devoted to a discussion of the etiology, pathology, and diagnosis of ankylosis and the importance of the functional position in the treatment of joints. By this phrase the authors would express that position in which a joint, though fixed, is most useful—such as the abducted and slightly flexed position of the humerus in shoulder ankylosis, which favours compensatory movements between the scapula and thorax. For each of the joints of the limbs there is such an optimum position of ankylosis, and the authors describe and discuss these positions with authority.

In the early days of attempted arthroplasty various substances were introduced into joints with a view to preventing reunion of the bone-ends, but these substances, if not extruded as foreign bodies, generally led to renewed ankylosis. The list of such substances is a long one, and includes wood, gutta-percha, celluloid, metals, and even gold foil, as tried by Keetley. Animal membranes came next, and of these the chromicized swine's bladder introduced by Baer of Baltimore is still used with success, but of late autogenous free fascia has very generally superseded it. Murphy, who introduced this material, laid stress on the value of a layer of fat on the fascia; moreover, he did not dare to use a free fascial graft, not trusting it to survive without a nutrient pedicle. To Kirschner is due the credit of suggesting, and to Payr of actually using, a free fascial flap in an operation of arthroplasty of a knee. Whatever technique is followed, the most rigid antiseptic and aseptic precautions are necessary, as is the avoidance of needless injury to the soft parts. The health and age of the patient and the nature of his occupation have a great importance in deciding for or against arthroplasty. One of the authors' successful cases was in a man of 50 whose calling made riding on horseback necessary. Again, ankylosis of several joints may make operation advisable, whereas it might not be if only one joint is fixed. For instance, ankylosis of both hips is such a crippling disability that a good deal of risk may justifiably be run in mobilizing one of the joints.

Arthroplasty of a joint such as the knee cannot be expected to be successful unless the muscles round the joint are in good condition or capable of being restored to good condition. To try to reconstruct the ligaments of a joint is generally hopeless, and it is to the muscles that the surgeon and patient must look for the control and stabilization of the newly formed articulation. Nevertheless, as the authors rightly point out, in such a joint as the hip the capsular tube is of great importance, and all remains of it are worth preserving.

The authors consider that although arthroplasty is feasible in many joints, the procedure should, generally speaking, be confined to practically five joints only—namely, the temporo-maxillary, the elbow, the knee, the hip, and the first metatarso-phalangeal joint. (The last-named seems hardly worthy of inclusion, considering how excellent are the results of free excision of the metatarsal head.) Nevertheless, the procedures for operation on the shoulder-, wrist-, and finger-joints are described, though it is stated that the two former seldom call for it. The results in suitable cases are good. Arthroplasty, as the authors say, cannot, of course, restore the joint to normal. Range of movement has often to be sacrificed for stability. "Roughly we may say that the new joint will have smooth motion, usually to within 75 to 90 per cent. of normal" (p. 57). But in the case of the knee the surgeon should, in our opinion, be well satisfied if he recovers 50 per cent. of the normal range of movement combined with stability.

After useful discussion of general principles and their application, the authors go on to describe the performance of arthoplasty on various joints, and the last three-fourths of the book are taken up by such descriptions, together with a short chapter on the prevention or minimization of ankylosis. This, although not quite germane to the subject, contains valuable hints, the fruit of ripe experience.

The book is well illustrated, and forms a very trustworthy guide to the practice of arthroplasty.

[1] *The Mobilization of Ankylosed Joints by Arthroplasty.* By W. Russell MacAusland, M.D., and Andrew R. MacAusland, M.D. Philadelphia: Lea and Febiger. 1929. (6 × 9¼, pp. vii + 252; 154 figures. 4 dollars net.)

MEDICAL ELECTRICITY.

THE sixth edition of Dr. E. P. CUMBERBATCH's *Essentials of Medical Electricity*[2] is not only larger than its predecessors, it is in many ways more attractive. In its present form the work should serve both as a textbook for the student and general practitioner, and as a reference-book for the specialist. The author has furthermore kept in mind the needs of candidates for admission to the biophysical assistants' roll, and has included careful statements about the limitations of electrical treatment and the precautions that must be taken in administering it.

By comparing the present with previous editions it is possible to obtain some idea of the advance that has occurred in recent years in the various aspects of electrotherapy—in theory, in technique, and in the range of its useful application. One paragraph from the introduction deserves to be quoted in full: "For the intelligent practice of medical electricity a sound knowledge of physics and the working of apparatus is necessary, for without it the principles of the subject, and even the meaning of the terms in everyday use, will not be understood, and it will be impossible to discover and put right simple failures of the apparatus when they occur." Not uncommonly a piece of apparatus is allowed to fall into disuse, for no better reason than that at some time or other it has "gone wrong" and the practitioner has not known how to discover the cause of the breakdown. Dr. Cumberbatch does much in the present edition to explain the correct wiring for a number of the currents used, but further guidance on the methods of seeking and correcting faults might with advantage be incorporated in later editions.

The illustrations of apparatus are taken from manufacturers' blocks, but we believe that reproductions of specially made photographs with suitable legends would be more helpful to students, though perhaps this would make the book more expensive. The kind of photograph we have in mind is the so-called "close-up"; such an illustration could show many useful points, and appended to it might be a few words of practical instruction—for example, in a diathermy machine using an open tungsten

[2] *Essentials of Medical Electricity.* By Elkin P. Cumberbatch, B.M.Oxon., D.M.R.E.Camb., M.R.C.P. Sixth edition, revised and enlarged. London: H. Kimpton. 1929. (Demy 8vo, pp. xvi + 445; 116 figures, 11 plates. 15s. 6d. net.)

spark gap, a reminder that the gap would require careful adjustment every now and then, and should not be looked at with the naked eye for more than a few seconds at a time.

The absence of the word "endothermy" from an otherwise copious index will at first sight seem curious in a work brought so thoroughly up to date; but reference to the section dealing with the "use of high frequency currents for cutting tissues" shows that, while the author is familiar with all that is claimed for these currents of sustained oscillation, he has deliberately decided not to add yet another name to those of the currents used in electrical treatment. Dr. Cumberbatch writes in an attractive manner, and his work is a credit not only to himself, but to the English school of electrotherapy.

FOODS AND FOOD VALUES.

THE fact that the third edition of Professor SHERMAN'S *Chemistry of Food and Nutrition*[3] has been reprinted four times since its issue in 1926 gives sufficient evidence of its general usefulness and popularity. Since this subject attracts much interest, outside the medical profession as well as within it, it is of considerable importance that textbooks should be written in a careful and well-balanced style, and that their authors should avoid prejudiced or doctrinaire statements. Professor Sherman's book is certainly well balanced and unprejudiced. He has, moreover, included a large amount of material in a relatively small compass, in spite of the fact that he permits himself, in many places, rather long, and perhaps rather superfluous, verbatim quotations from various authors. On one point, however, we feel that we must criticize him. It is a matter of debate whether, in a work of this kind, it is desirable to cite individual workers by name or to give references to original papers. But if such references are made, then it is the clear duty of the author to take pains to make them accurate. Professor Sherman has signally failed to do this. A few of the more glaring examples will be sufficient. On page 77 the discovery that tryptophane is an essential food constituent is attributed to Osborne and Mendel, while on page 76 Rose and Cox are credited with a similar discovery with regard to histidine. Hopkins had, of course, established the facts several years earlier than any of the workers mentioned. Provided that the facts are established personal priority is perhaps of small moment; still, inaccuracies of this kind should be avoided, for they can only cause embarrassment to those who have thrust upon them claims which they would never dream of making for themselves. The preface to the third edition is dated May, 1926, but the impression before us is dated 1928, and is said to have been rewritten; it is unfortunate, therefore, that the information on such an important subject as thyroxine is obsolete and incorrect.

Food Values in Practice,[4] by Miss E. M. DOBBS, might perhaps be more fully described as a textbook of domestic economy, since the matters discussed range far beyond questions of the caloric or monetary values of foodstuffs. Besides dealing with questions of kitchen arrangements, food storage, and cooking routine, she has something to say on the general arrangement of the family budget, and much about cooking; indeed, nearly a third of the book is devoted to recipes for dishes for everyday life and for invalids. On the whole the work is admirably clear and simple. The author evidently knows what she is talking about, and her advice and suggestions should prove of real help to housewives keen enough to profit by them. The most serious fault which we have to find is the introduction of loose statements about debatable points in physiology and medicine. We find it stated in separate passages that protein, fat, and phosphorus are foods especially related to the production of nervous energy. In point of fact very little information is available as to what foodstuffs are used either by nerve or brain tissue, and such slender evidence as exists points rather to the importance of carbohydrate. Statements on such matters seem, in any case, rather out of place in a work of this kind, and perhaps the author would have done better to keep more closely to the well-established facts of her subject.

[4] *Food Values in Practice*. By Ethel M. Dobbs, M.A.Lond. With a preface by Henry R. Ellwood, C.M.G., M.B., F.R.S.E., D.P.H. London: University of London Press. 1929. (Cr. 8vo, pp. xvi + 230. 4s. net.)

FAMILIAL NERVOUS DISEASES AND DYSTROPHIES.

IT is most appropriate that the preface to Dr. O. CROUZON'S collected studies on the familial diseases of the nervous system and dystrophies[5] should have been written by Professor PIERRE MARIE, a predecessor of the author at the Salpêtrière, and the original describer of a number of the diseases dealt with in this well-illustrated volume. The work is composed of two main parts, the first and larger being devoted to the familial diseases of the nervous system, and the second to familial dystrophies. There is also a short section on diseases exceptionally familial, which includes accounts of familial tabes dorsalis, exophthalmic goitre, and von Recklinghausen's neurofibromatosis; the last subject is dealt with in considerable detail, and its occasional hereditary as well as familial incidence is brought out. All the articles have been previously published during the last twenty years; the longer ones, which deal with familial nervous diseases, and so come early in the volume, are reprinted from *Le Nouveau Traité de Médecine*, edited by Roger, Widal, and Teissier, or from the proceedings of various congresses, while the shorter articles, which are mainly records of rare clinical cases, have appeared in journals and the proceedings of medical societies. Some of the articles were brought out with collaborators, and a valuable account of atypical nervous diseases, published under the direction of Professor Pierre Marie, is reprinted in part and is well illustrated with figures, among them a drawing by P. Richer, who was so closely associated with Charcot. In an account of the familial infantile encephalopathies there is a full description of Wilson's disease, or hepato-lenticular degeneration, the literature being epitomized. A large amount of original observation made at the Salpêtrière has thus been brought together in a convenient form, and in addition the literature of the subject has been analysed. A pleasing feature of this book is the frequent reference to British writers.

PRINCIPLES OF HEREDITY.

MR. JAMES WILSON'S *Manual of Mendelism*[6] is primarily written for the purpose of providing agricultural students with a clear and simple exposition of the principles of heredity. The author has obviously put himself to great trouble to present his subject in plain language and to free it as much as possible from the more hypothetical aspects of the science of genetics. It would seem, however, that he has somewhat overdone the simplifying process. He has left out what he considers to be the difficult links in the chain of explanations which are now available to enlighten us on the transmission of hereditary characters. The result is that inadequate information on many points leads to confusion rather than to simplicity. Genetics is a subject which is very easy to understand and remember when properly reasoned out, but with the omission of an explanation of the mechanism of heredity it is impossible for the student to reason out inheritance for himself with the result that the difficulty of understanding the subject is increased.

In the first chapter appears the statement that "a dominant and its recessive cannot be carried by the same seed." To the trained geneticist it is obvious that the author uses the word "seed" instead of "gamete," but to the uninitiated this looseness must lead to confusion. A chapter on the mechanism of heredity would have enabled the author to explain such points with greater crispness and accuracy. In the same chapter he says that

[5] *Études sur les Maladies Familiales, Nerveuses et Dystrophiques*. By O. Crouzon. Preface de M. le Professeur Pierre Marie. Paris: Masson et Cie. 1929. (6¼ × 9, pp. viii + 325; 90 figures. 55 fr.)

[6] *A Manual of Mendelism*. By James Wilson, B.Sc. Second edition. London: A. and C. Black, Ltd. 1929. (Post 8vo, pp. xi + 152. 5s. 6d. net.)

"dominants cannot be combined with their own recessives." It is obvious that a student must be left in doubt as to the proper significance of this statement, for no clear explanation is given in the book as to the difference between phenotype and genotype. In the chapter headed "Observations and deductions" the author writes: "If hybrids are mated with their pure parental kinds, as many kinds are produced as are produced when the hybrids are mated with each other." This is true only in the phenotype when the back cross is made to the recessive parent, and as regards the genotype the statement is quite wrong. When dealing with what he calls "coupling or linking," Mr. Wilson speaks of factors tied to the female factor or the male factor as the case may be. Sex linkage demonstrated in this way must be uninteresting and incomprehensible to the student, in contrast with the ease with which sex linkage can be explained when use is made of the chromosome basis of inheritance.

Apart from looseness and inadequacy of the scientific information given in this book, there is—particularly in the later chapters—ample evidence of the author's fullness of knowledge concerning the observed facts in breeding practice.

NOTES ON BOOKS.

IN preparing the second edition of his *Surgical Pathology*[1] Dr. WILLIAM BOYD has made considerable changes and additions. The chapters on the thyroid gland and the stomach have been rewritten, as also have those on the etiology of tumours, the melanomata, lymphosarcomata, tumours of the testicle and of the kidney, the so-called carcinoid tumours of the appendix, and on endometrial implants. The chapter on surgical bacteriology has been altered in scope, and is now concerned with suggestions as to how the surgeon may utilize the assistance of the laboratory, rather than with a statement of elementary bacteriological facts. The chapter on the spleen has been recast. New material has been added in connexion with tissue cultures, pre-cancerous lesions, carotid body tumours, tumours of the xanthoma group, the reticulo-endothelial system, pituitary tumours, diverticulitis, cholecystitis, and rickets. The researches of Bailey and Cushing on tumours of the glioma group have been incorporated, without, however, inflicting on the overburdened student the whole of the fourteen names introduced by those observers in their description of the several varieties. It will thus be seen that no trouble has been spared to bring this practical and well-written book up to date.

In his *Urological Nursing*[2] Dr. DAVID M. DAVIS, assistant professor of urological surgery in the University of Rochester, has catered for nurses dealing extensively with urological cases. As he points out in his preface, at one time the rough-and-ready methods and manners of some of the early practitioners of genito-urinary surgery set this specialty somewhat apart from other branches of medicine and surgery. The primitive methods of hospital care, the infected wounds, and the offensive odour of the urological wards led many nurses to avoid, if possible, this type of work. Happily, conditions have now changed, and both the operative treatment and the after-care of urological cases are advancing by leaps and bounds. In no type of case is nursing more important than in the after-treatment of a prostatectomy, and urological nursing in general is becoming an important part of a nurse's training. The first half of the book contains very full descriptions of the instruments and equipment used in urology. The second half is devoted to such procedures as cystoscopy, renal functions tests, and operations in general. If any criticism is to be made it is that, while much attention has been paid to instruments and equipment, little space is given to the details of nursing and after-treatment.

We have received for review the fifth volume, or first supplemental volume, of *Tabulae Biologicae*.[3] The object of this book, which is published by W. Junk of Berlin, is to provide biological workers with tabulated data in the same manner that the work of Landholt and Bornstein provides data for the chemist and physicist. The first four volumes dealt with the physiology and anatomy of animals; they appeared between 1925 and 1927, and were indexed in the last volume. The present volume is devoted to botanical data, and contains an independent index, which indexes the fifth volume and also gives references to botanical data in the previous volumes. The first third of the volume under review is concerned with the biology of algae, of bacteria and fungi, and with the general forms and functions of the higher plants; the middle third is devoted to the biochemistry of plants and to periodicity phenomena; while the last third of the book is occupied by a section of 230 pages on the experimental ecology of plants. It is hoped that the present volume will prove as great a convenience to botanists as its predecessors have been to physiologists.

The dedication volume[4] of the Montgomery Ward Memorial of the Northwestern University Medical School, Chicago, edited by the dean, Dr. Irving S. Cutler, consists of five parts. The first, which is introductory, contains short biographies of Montgomery and Elizabeth Ward, who left the school eight million dollars for the creation of an institution for the advancement of medical science, Mr. Charles Hallett Thorne, who helped Mrs. Ward in planning the memorial, and Alexander McKinloch, the gallant young soldier killed in France, to whom the Chicago Campus of Northwestern University is dedicated. Part 2 deals with the history of the Northwestern Medical School, which was opened in 1857, and the Ward memorial buildings and McKinloch memorial campus. Part 3 contains dedicatory addresses concerning the distinguished alumni of the Northwestern University on the occasion of the unveiling of their portraits, and accounts of the library, museum, and laboratories. Part 4 contains general addresses on problems in medical education and the fostering of clinical investigations, delivered by Charles H. Mayo, Leonard G. Rowntree, and others, while Part 5 consists of papers on various medical and surgical subjects.

A pocket outline of the routine laboratory work performed in the Massachusetts General Hospital was published in 1922, and Drs. R. B. WHEELER and F. T. HUNTER have carefully revised this *Laboratory Manual of the Massachusetts General Hospital*,[11] the original text having been brought up to date. The scope is comprehensive, ranging from the collection and examination of specimens to certain diagnostic procedures and details of therapeutic and prophylactic technique, including small-pox vaccination. The hope is expressed that this little book may assist the medical practitioner in his daily work.

In his small volume of *Poems*,[12] described as "Verses topical and gay to while a sleepless hour away," Dr. J. L. BASKIN provides fifteen short pieces dealing with various subjects, such as an expanded paraphrase of the Lord's Prayer, Captain Matthew Webb's swim across the Channel, the first Atlantic aeroplane flight from east to west, a hurdle race, and the survival of the fittest. In the last of these the reader is presented with an interesting, if somewhat cryptic, reference to Sir Arthur Keith. Another medical writer of verse, Dr. LEONARD LEY of Great Yarmouth, has published privately a collection of nearly fifty short poems in various metres and on very diverse aspects of life.[13] Though love and pathos predominate, war experiences are treated with an attractive swing. The impression left by these verses is very pleasant, and encourages the hope that Dr. Ley will continue in well-doing, and again communicate the poetic fruits of his philosophy to his friends.

The *Minutes of the General Medical Council and of its Various Committees* for the year 1929 have been published, with fifteen appendices, in a volume which includes reports of the two sessions of the General Medical Council, of its Executive and Dental Committees, and of the meetings of the English, Scottish, and Irish Branch Councils. The appendices comprise reports of the Public Health, Pharmacopoeia, Education, Examination, Dental Education and Examination Committees, and a report on the education of medical students in midwifery and gynaecology. The *General Index* to the Minutes of the General Medical Council and of its Executive and Dental Executive Committees, and of its three Branch Councils, from 1905 to 1929, relating to volumes xl to lxvi, follows the plan of the previous issue.

THE VACCINATION PROBLEM.

PAPER BY PROFESSOR MAJOR GREENWOOD.

THE vaccination controversy, ideally conducted, would, one might imagine, need nothing for its final settlement except tables of figures and mathematical symbols. For such a controversy the proper arena would be the neutral territory of statistics, within which the problems could be set out in orderly fashion, the data assembled, and a solution found by the application of pure reason. In actual practice this method has not proved very popular; figures have, indeed, been imported into the discussion, but too often for use as missiles. Far more popular have been attempts to settle the dispute by deciding whether Edward Jenner was a genius or a charlatan, a scientific worker or an ignoramus; or rather, by proving that he was the one or the other, according to the view of vaccination held by the person producing the evidence. So large a part has Jenner's character played in the vaccination controversy that even Professor Major Greenwood, F.R.S., whose bias—if a statistician may be said to have a bias—is towards the view that the practically important issues of the controversy are statistical, devoted a large part of his recent paper on the vaccination problem to a discussion of the conflicting estimates of Jenner's personal merits, making in his turn a psychological re-interpretation in the light of facts that have been recently established. The paper was read before the Royal Statistical Society on February 18th, and will appear in full in the *Journal* of that society.

THE WORK OF JENNER.

Why does so much provaccinist literature consist of glorification, and so much antivaccinist literature of vilification, of Jenner? Probably, suggests Professor Greenwood, because the protagonists on both sides realize that if it can be established that Jenner thought, watched, and experimented for many years, laying the foundations of every statement he advanced with patience, caution, and modesty, it would be reasonable to assume, not indeed that vaccination *must* be an effective communal defence against small-pox, but at least that its failures in this respect might be due to extrinsic difficulties which we should seek to remove, and not to intrinsic defects. The provaccinist estimate of Jenner is based largely on data provided in 1838 by his friend and biographer, Dr. John Baron; the antivaccinist is happy to accept the judgement expressed some half a century later by Dr. Charles Creighton in his work *Jenner and Vaccination*. Creighton, to whose scholarship, literary gifts, and disinterested service of truth Professor Greenwood pays generous tribute, had read Jenner's writings and perceived that the work described by the great sanitarian John Simon as "a masterpiece of medical induction" was, in fact, a very amateurish achievement. The induction itself—namely, that those who had had cow-pox were thereby rendered incapable of taking small-pox—seemed insecurely founded, while in the experimental part of the research he failed to find those precise and unambiguous descriptions that characterize really first-rate work. Creighton saw that the Jenner of Simon and Baron was a mythological construction, and began to sketch a far more lifelike character—a pleasant lad with a taste for natural history and an inquiring turn of mind. But even at this stage, says Professor Greenwood, the scholarly biographer, in dealing with Jenner's paper on the habits of the cuckoo, was betrayed by his temperament into what has proved to be a complete error. Jenner, it may be recalled, contributed to the *Philosophical Transactions of the Royal Society* a paper in which he asserted that the fledgeling cuckoo itself, not the foster-mother, ejects the eggs or foster-fledgelings from the nest, and has a back specially designed for this purpose. Jenner's statement, according to Creighton, was false; and the whole research he summed up in these words: "Jenner's cuckoo paper contains a few credible and prosaic facts; but the greater part of it and all that part of it which is best remembered is a tissue of inconsistencies and absurdities." Jenner's dabbling in natural history would not at first sight seem to be of great consequence, but in fact antivaccinists have argued that vaccination cannot possibly protect against small-pox because Jenner told fibs about cuckoos. According to Professor Greenwood, however, who consulted Dr. Manson-Bahr and Mr. R. H. Burne on the subject, modern observations completely bear out what Jenner said about the habit of the young cuckoo, and suggest that his assertion about a transitory peculiarity of structure in its back is probably correct. In this matter, therefore, it appears that it was not the slap-dash country doctor, but the scholarly biographer, who was writing nonsense.

Continuing his analysis of *Jenner and Vaccination*, Professor Greenwood says that it is not until we reach the publication of Jenner's "masterpiece of medical induction" that Creighton really begins to compete with Simon and Baron in the manufacture of myths. The "masterpiece" bore on its title-page the words *Inquiry into the Causes and Effects of the Variolae Vaccinae*, and behind those words "variolae vaccinae"—in which [illegible] blends with a metalepsis—Creighton saw a deep design, an "unblushing invention" to trick the whole medical profession into the belief that cow-pox was, if not small-pox, at least its own cousin. Naturally, says Professor Greenwood, a man who could combine a synecdoche with a metalepsis would be capable of anything! And, with this clue to Jenner's baseness, Creighton created a character which might pass for the quintessence of rogues, whinery. On the other hand, Creighton's first impression of Jenner as a badly educated, inquisitive young country doctor, receptive of ideas but uncritical, may not have been far out.

Let us suppose (Professor Greenwood continues) that such a man, undaunted by the mockery of his profession, did think there might be something in the old wives' tale about cow-pox and small-pox. He collects a few records, makes a few amateurish experiments and observations, and on account thinks the results worth publishing. He publishes them, and [illegible] all probability—he attracts a great deal of attention, is taken up and also criticized by much more experienced than himself. His doctrine is attacked and defended by professional men of much higher standing than himself, and in intellectual methods he has neither the knowledge nor the practical experience to enable him fully to understand. It would be very human if such a man, suddenly become famous for the ideas which had been laughed at by his fellow practitioners in the West taken very seriously indeed in London, should deceive himself as to the extent to which mere conjecture, guesswork, contributed to his "discovery," and should *de facto* seek to improve upon the truth. That seems to be primarily much more probable character of Jenner than either Baron's or Creighton's.

But he is not disposed to stress very heavily Creighton's deficiencies as a psychologist; Creighton, he points out, deserves every credit for his demonstration that neither Jenner nor anybody else, down to the date of Creighton's own book, had shown, experimentally or otherwise, that cow-pox was biologically akin to small-pox; and it must be admitted that to the end of the nineteenth century vaccination as a prophylactic rested wholly upon an empirical basis. Early in the twentieth century, however, a number of investigators demonstrated that, as a matter of biological fact, Jenner's assertion that cow-pox and small-pox were closely akin was, like his statement about the habits of the cuckoo, true. In 1902 Dr. S. Monckton Copeman produced typical vaccinia after passaging variola virus through a monkey, and then vaccinating a calf from the monkey. Since then it has been possible to demonstrate the affinity of variola and vaccinia by methods of quantitative precision, which, Professor Greenwood says, "all of us, whatever our opinions on the vaccination problem may be, regard as outside the field of rational controversy. . . . In other words, that kinship between the cow disease and the disease of man which Jenner did not prove has now been very definitely proved, and the many thousands of pages which have been devoted to the virtues or vices of Jenner or to denouncing the folly of trying to protect against one 'disease' by producing another 'disease' are of purely historical interest."

VACCINATION AS AN INDIVIDUAL PROPHYLACTIC.

Although all large collections of data have appeared to show that vaccinated persons exposed to the same risk of small-pox as unvaccinated persons have been attacked at a lower rate, and that those attacked have died at a lower rate, judicious critics have been by no means willing to assume correlation to imply causation. In dealing with attack rates, for example, the question whether the vaccinated and unvaccinated were indeed equivalent in all relevant respects other than in their vaccinal state is not easy to answer; the difficulties with respect to fatality rates are not quite so great, and those who have been unwilling to accept the figures at their face value have had resort to subtle arguments. Professor Greenwood, to illustrate this subtlety, cites passages from Creighton's *History of Epidemics in Britain*, in which that author deals with Gregory's observation that in the epidemic of 1825 the fatality rate on the vaccinated attacked was 8 per cent., and upon the unvaccinated attacked 41 per cent.

> He (Creighton) remarks that "There are various ways of apportioning a general average. The presence or absence of cow-pox scars is one principle, which could have been used to break up the 25 per cent. of 1777, or the 39 per cent. of 1781, or the 33 per cent. of 1795 into two component parts." He then notes that one thing common to all times is different fatality at different ages, and remarks that "all the deaths in the 8 per cent. division of 1825 were between the ages of 18 and 27; the ages of the 41 per cent. division are written in the books of the hospital." Finally, he remarks that "However manifold the cutting up of a general average, some divisions would be identical, corresponding to natural lines of cleavage" (Creighton, 1891-94, II, 595). . . . Whether Gregory's evidence were or were not vitiated by a high correlation of vaccinal state and age, data since his time undoubtedly show, *prima facie*, a great advantage in respect of fatality within age groups.

Professor Greenwood here inserts a table of fatality rates among the vaccinated and unvaccinated at various age groups from 5 to 40, which brings out clearly that the advantage of the vaccinated cannot be due to a fortuitous concurrence of age and vaccination groupings. To explain away these figures it has been suggested that the responsible variable is social class, the vaccinated belonging to the better housed and better fed stratum of the community, and therefore being more resistant to any acute disease. Professor Greenwood recalls that an investigation of this hypothesis within a limited field was conducted by the late Dr. W. R. Macdonell, and the results published a quarter of a century ago in *Biometrika*:

> Dr. Macdonell used data supplied by the late Dr. John Brownlee which consisted of particulars relating to 242 vaccinated and 29 unvaccinated males admitted to the Belvidere Hospital, Glasgow, in 1900-1 suffering from small-pox. Macdonell grouped the occupations in various ways thought to correspond to social status, and tested association between social status and vaccination and between social status and fatality by means of the tetrachoric *r*. Having regard to the probable errors of the computed coefficients, it appeared that there was no sensible association between social status and fatality. Macdonell concluded that "The Glasgow statistics do not go very far, but as far as they go they do not justify the statement: that the apparent protection of vaccination is due to the unvaccinated belonging to classes of lower status which have a far smaller power of resistance to the disease than the better nourished classes of a higher status in which the members are more generally vaccinated."

The evidence, suggests Professor Greenwood, though not disproving the *a priori* probable belief that the resistance of the well fed and well housed is greater than that of the ill fed and badly housed, is sufficient to throw the onus of proof on those who maintain that there is a practically complete correlation between vaccination and social well-being, or between social well-being and escape from death when attacked by small-pox, an onus which they have not discharged. No serious critic of the orthodox faith could deny that numerical statements of lower attack and lower fatality rates of vaccinated persons have been obtainable whenever the distinction between the vaccinated and the unvaccinated has been recorded; some, indeed, have asserted that the published tables are disingenuously compiled; but for various reasons—for example, that even adding the "doubtfuls" to the vaccinated category does not affect the broad comparison—the scientific opponents of vaccination have attached no importance to such contentions and have confined themselves to providing special explanations. An interesting example cited by Professor Greenwood relates to the many statistical tables that purport to show how the fatality of small-pox in the vaccinated diminishes *pari passu* with the number of vaccination scars, or with the size of the cicatrized area. In criticism of such tables Creighton said that as the nature and intensity of the scarring was a function of the texture of the skin, the deduced coefficients had no bearing on the point in dispute. This argument Professor Greenwood admits he could not meet till it occurred to him that here one had merely another violation of the rule *Entia non sunt multiplicanda praeter necessitatem*, for neither Creighton nor anyone else had provided evidence that the fatality of small-pox in unvaccinated whites really was correlated with the histological character of their skins.

It is certainly not impossible (he continues) that the *prima facie* explanation—namely, that the vaccinated die of small-pox at a lower rate than the unvaccinated because they *are* vaccinated—could be true; we can only avoid the inference by inventing a series of special explanations, sometimes alleging a class difference, sometimes an age difference, etc.; we do not act in that way in other equally important practical matters. We believe, for instance, that the candidate in examinations who obtain more marks than the pass standard are, in the main, better educated than those who are "ploughed"; the facts that there are a host of reasons other than ignorance which may contribute to failure, and that there is certainly not perfect correlation between the grading by an examination and the real ranking of knowledge (not to speak of power to use knowledge) does not shake our general belief that the examination test is of real value. I conclude, therefore, that orthodox opinion upon this particular point is sound: that vaccination has been shown to confer some protection against the risk of dying from small-pox. But *how much* protection? Given two persons, the one efficiently vaccinated the other not, but the two otherwise *in pari materia*, given that both are infected, is the risk run by the vaccinated person a half, a quarter, or what fraction of the risk of the unvaccinated?

This question, he believes, cannot be answered, and he devotes a great part of his paper to a highly technical presentation of the statistical reasons why it cannot be answered. Expressed briefly, his conclusion is that any statistical theory of immunity that can be scientifically reconciled with the biological facts must have as a corollary a very high correlation between the fatality rates of immunized and unimmunized in different epidemics. The published data of small-pox do not adequately fulfil this condition, a fact that may be due to the heterogeneity of the data—differences of sex, age, social class, length of interval since vaccination, etc.—which, acting as observational errors, must water down the correlation. The data are adequate to demonstrate a substantial advantage to the vaccinated, and though in Professor Greenwood's view this advantage is intrinsic, not accidental, he cannot offer more than a crude approximation to its quantitative value. Precision, he holds, can only be attained by an *entente cordiale* between experimental and statistical methods.

VACCINATION AND THE EPIDEMIOLOGY OF SMALL-POX.

Professor Greenwood now turns to examine the contention that the general decrease of small-pox throughout the nineteenth century was in consequence of the introduction and dissemination of vaccination. Two arguments have been developed in support of this contention. The first is based on the fact that while during the seventeenth and eighteenth centuries small-pox in London was perhaps the most formidable of epidemic killing diseases, in the nineteenth century there took place a great improvement, utterly disproportionate to the improvement that had been noted in other epidemic diseases—for example, in measles, scarlet fever, diphtheria, and whooping-cough. From this fact it has been assumed to follow that the remarkable excess of improvement in small-pox must be attributed to some cause or causes other than sanitary reform—which would affect all epidemic maladies equally—the only reasonable cause being vaccination. The second argument has based itself on a comparison between a history of small-pox in well and less well vaccinated States,

commonly between England and Wales and the German Empire. In the period 1900 to 1925 inclusive the latter, with a population half as large again as that of England and Wales, has had little more than half as many deaths from small-pox, an advantage attributed by supporters of vaccination to the fact that in Germany during the last generation primary vaccination has been more nearly universal than in England and Wales, while revaccination has been a legal obligation.

The most obvious weakness of the former argument, Professor Greenwood points out, is that in the rise, decline, and fall of scarlet fever within the nineteenth century has occurred at least as remarkable a secular evolution as in small-pox. This argument, however, does not seem to him to weaken the force of the comparison of English and German experience, and he sees no fallacy in the contention that a really drastic system of vaccination and revaccination is more efficient in preventing small-pox than the Laodicean practice in our own country. Creighton saw in the secular evolution of small-pox merely an example of Sydenham's remark that diseases, like empires, rise, decline, and fall; and he brought together evidence that long before the introduction of vaccination both the fatality and the age incidence of small-pox had varied greatly. On this Professor Greenwood comments:

In the eighteenth century, and early in the nineteenth, small-pox was mainly a disease of children. Even as recently as 1851-60 the rate of mortality in no age group later than 5-10 years amounted to one-fifth of the rate at 0-5. By 1871-72 the relative predominance of the age group 0-5 was considerably reduced; for instance, the mortality rates in the age groups 15-25 and 25-35 were almost a third of the rate at 0-5. Orthodox opinion attributed the change to the fact that the proportion of young children recently vaccinated was certainly much greater than that of adults. Creighton attributed it to two factors; first, to the competition in early life of the other great zymotics, one of which, scarlet fever, was certainly more deadly in the middle years of the nineteenth century than a generation before, and, secondly, to an epidemiological obsolescence of the disease; it would, he said, "be a not incorrect summary of the incidence of small-pox in Britain to say that it first left the richer classes, then it left the villages, then it left the provincial towns to centre itself in the capital; at the same time it was leaving the age of infancy and childhood. Of course, it did none of these things absolutely; but the movement in any of these directions has been as obvious as in any other."

So far as the age distribution is concerned the data of the only large-scale prevalence of classical small pox in England, since Creighton's work, that of 1901-2, followed the rule with a partial exception; the rate of mortality at 6-10 was a smaller fraction of that at 0-5 than in 1871-72—namely, 31 per cent. instead of 50 per cent., but at later ages the rates as percentages of the rate on 0-5 were much higher than in 1871-72; 79 per cent. at 25-30, 80 per cent. at 35-40, 52 per cent. at 45-55, and 24 per cent. at later ages. Since by 1901-2 the competition of scarlet fever for a share of youthful victims had diminished greatly, Creighton's first factor is not likely to have had much effect. There remains his contention that small-pox was becoming obsolete, and that a differentia of obsolete diseases is that they cease to attack the young. In my opinion that statement is true; there is some evidence that the age incidence of plague in England shifted towards the adult region of life as plague left the country districts and concentrated on the towns, and there is, of course, conclusive evidence that this has happened in the last two generations in the fatal incidence of pulmonary tuberculosis—namely, that mortality first began to decline in the earlier age groups and only fell in the later age groups some time afterwards. This has also happened in scarlet fever. Creighton was quite justified in drawing attention to this important point; but why should we not believe that the dissemination of vaccination has been *one* of the factors of this decay?

Some advocates of vaccination have gone further, claiming not only that vaccination had been a modifying factor of the epidemiological character of small-pox, but that the small-pox of the nineteenth century among the unvaccinated was epidemiologically identical with that of the eighteenth century; thus, the late Dr. John McVail said, and illustrated from the statistics of small communities, that normally, in the eighteenth century, epidemics of small-pox occurred at intervals, running through all the children who had been born since the last visitation, and levying the kind of death toll which was exacted from the unvaccinated in the nineteenth century. There is, says Professor Greenwood, reason to think that this hypothesis is substantially true. It can be proved that even in the eighteenth century epidemic small-pox might be extremely mild. Sydenham, as his comparison of the irregular and the regular small-pox illustrates, had observed this in the seventeenth century; Murray of Göttingen, in the middle of the eighteenth century, noted the curious benignity of certain Swedish epidemics. There is sufficient evidence, however, that small-pox in the eighteenth century was, as a rule, a very infectious and deadly disease. But in the nineteenth century the introduction of small-pox into a community, wherein infant vaccination was the exception rather than the rule, has not been regularly followed by a disastrous epidemic. In illustration Professor Greenwood cites data from the history of small-pox in Australia, recently published by Dr. Cumpston:

In New South Wales a large proportion of the population was not vaccinated in infancy. Thus in the decennium 1871-80, 234,115 births were registered and 70,494 vaccinations. Victoria, on the other hand, was well vaccinated; in the ten years which preceded the outbreak of small-pox in Melbourne in 1884 the ratio of vaccinations to births was 217,153 to 267,300. Both the relatively well-protected and the relatively ill-protected States have had outbreaks of small-pox; in neither has there been a serious conflagration. The epidemic of 1881-82 in Sydney is particularly instructive. Between May 23rd, 1881, and February 19th, 1882, 154 cases occurred in Sydney. It seems clear that before September 2nd, 1881, seventeen streets were infected—that is, the disease was wide-scattered through the city. From accurate data respecting the experience later than September 2nd (the statistics of the first part of the epidemic have perished) it seems that the fatality of the disease was of normal severity—namely, a fatality rate of 25.9 per cent.—but the ratio of cases to exposed to risk was low. Unfortunately the vaccinal state of the exposed to risk is not recorded, but the following inference seems justified—namely, that the presence in a populous city of a normally virulent strain of infection did not, in spite of the low level of herd protection, lead to any remarkable results. Two comments are, however, necessary. The first, that the mere ratio of vaccinations to births is not a satisfying measure of the extent of protection; the second, that, during the currency of the epidemic, a great deal of vaccination was done (more than 61,000 vaccinations are recorded in New South Wales in 1881). Victoria only experienced one serious epidemic, if, indeed, the adjective be justified, an outbreak (in Melbourne) with 56 cases and but 4 deaths, which was in 1884-85. The interest of this resides in the fact that, unlike the Sydney experience, there is evidence of a widespread dissemination of mild small-pox; this is interesting because vaccination was, it appears, much more widely used in Victoria than in New South Wales.

The rigidly orthodox, remarks Professor Greenwood, will perhaps hold that the experience of Victoria as compared with that of New South Wales is one more illustration of the value of vaccination, fewer lives having been lost in the former than in the latter. He himself would rather stress the fewness of the deaths in Sydney as a demonstration of the fact that a community wherein infant vaccination has been neglected is not, when brought in contact with an infection, mere dry wood through which the fire runs. If that were indeed the state of affairs in the seventeenth and eighteenth centuries he would conclude that the *genus epidemicus* of nineteenth century small-pox, in spite of the persistent fatality of the disease, differed from that of the eighteenth century. That the epidemic type of small-pox was indeed changing is made easier to believe because Australia is one of the many countries in which, within the past twenty years, small-pox has again changed very much. On this Professor Greenwood says:

In May, 1913, the new epoch was ushered in in New South Wales by the appearance of an unusual rash amongst the staff of a manufactory of underclothing in Sydney; this was diagnosed as small-pox, and extended sooner or later to no fewer than twenty-eight country towns and districts. In the year 1913, 1,073 cases were recognized in the State (1,017 in Sydney); in 1914, 445 cases were found in the metropolis, 183 in other areas. In 1915 there were 41 cases in Sydney, 430 elsewhere; in 1916, 16 in Sydney, 92 elsewhere; in 1917 none in Sydney, but 119 elsewhere. This considerable prevalence differed essentially from any previous experience in its negligible fatality. In another respect, however, it followed the usual rule—namely, that the vaccinated were attacked at a lower rate. Although this statement cannot be directly

proved, the enormous disproportion of unvaccinated to vaccinated amongst the attacked (of 1,037 patients treated at the Sydney quarantine station in the six months ending January 31st, 1914, only 53 had been vaccinated) is cogent indirect evidence of its truth. As is well known, this epidemiological variety of small-pox is now widespread; its modern history can be traced back at least to 1895; its most usual name, alastrim, we owe to a prevalence in Brazil reported upon by Ribas in 1910. That is the type now prevalent in England and Wales.

PROFESSOR GREENWOOD'S CONCLUSIONS.

The cross-immunity experiments of Gordon and others seem to show conclusively that alastrim is biologically more akin to classical small-pox than to varicella, and whether the disease shall be termed alastrim, para-small-pox, variola minor, or just plain small-pox, seems very unimportant. On the other hand, says Professor Greenwood, if we could be sure that the present type of small-pox would become universal, vaccination as a prophylactic would soon be of purely historical interest, because the risk to the individual of vaccination, whether as a specific or merely procatarctic factor, is probably greater than that of the fashionable small-pox. But even if the prevalent type of small-pox can be trusted to breed true, there still exists side by side with it the old dangerous type. If, state supporters of vaccination, we deliberately abandon the nominally compulsory system, the level of herd immunity will fall still lower. The time will come when, this immunity having fallen below some critical value, we shall experience a reversion to the horrors of the eighteenth century. If, moreover, the prevalent variety is not fixed, but capable of breeding classical small-pox, the danger is intensified.

It is implicit in this argument that the exposure of an unprotected population to the risk of infection will probably lead to a serious, life-destroying epidemic. I have already pointed out that such experience as that of Sydney does not support the proposition. In his very important and frequently misrepresented treatise, Dr. Killick Millard has provided much stronger evidence to the same effect. His experience in Leicester has been that the frequent introduction of the infection of small-pox into a community within which infant vaccination had been systematically neglected did not lead to a widespread and murderous epidemic. With respect both to Sydney and to Leicester it can be urged that (1) neither community had a more favourable experience than many towns which, while making use of infant vaccination, had not reached the level of administrative efficiency which has honourably distinguished Dr. Millard's regime at Leicester; (2) that in both an appreciable proportion of the exposed to risk had actually been vaccinated. It remains, however, indisputable that the gloomy prophecies with respect to Leicester's epidemiological future which were made a generation ago have not been fulfilled (McVail, 1919; Millard, 1919). If it be said that the basis of the induction, that to neglect infant vaccination is not to incur an appreciable risk of severely epidemic small-pox, is slender, it may be retorted that the confident assertion that such neglect leads to disaster has an even slighter basis of accurately observed facts.

His personal belief is that unless compulsory vaccination and revaccination are enforced with a rigour hitherto unknown, the effect of compulsory measures upon the spreading and killing powers of the disease will be trivial; on the other hand, the price of compulsory vaccination on a scale likely to save lives must be paid in lives. He is not satisfied that the resultant saving of life must exceed the price paid and, on that account, he is a supporter of the policy advocated by Dr. Millard. "Those, I think a majority of my profession, who believe that the price to be paid would be trivial in comparison with the risk avoided (it would assuredly be much smaller than now exacted for the mere convenience and pleasure of driving fast motor-cars along our highways), would be unfaithful to the truth as they see it if they did not advocate a wholly different policy."

Nova et Vetera.

A DAY IN A DOCTOR'S LIFE.

THE medical man in fiction is not often a very convincing character to his brother practitioners in real life, whether he appears as a benevolent old *deus ex machina*, setting right all the squabbles of the village, as the brilliant and sometimes sinister surgeon who performs impossible operations, or as the joyous young scapegrace of the Bob Sawyer type. The reason for this lack of veri-similitude is perhaps to be found in the professional secrecy with which the doctor has surrounded himself; the atmosphere of mystery in which he used to perform his rites; and the ignorance of authors in the arcana of the medical craft. The doctor himself, as a rule, has neither the time nor the literary skill for weaving his experience into a romance.

Recently, however, a novel has appeared in which the author seems to have taken infinite pains with the portrait she has drawn; Miss Helen Ashton has succeeded in giving a vivid and true idea of the romance of medical practice, and in holding the reader's attention to the end of her description of a single day in the professional life of *Doctor Serocold*.[1] She adopts the modern psychological method of tracing the thoughts that run through the mind of the doctor as various patients or objects in his little provincial town come under his observation. The flow of thought through the mind, as continuous almost as the heart's beat, is not represented as the incoherent, disordered, and often muddy stream depicted by Mr. James Joyce. Dr. Serocold's thoughts run largely in the past, giving us a summary of his life's work, illustrated by vignettes of the lives of his patients and of his own aspirations and disappointments.

We are introduced to Dr. Luke Serocold at the age of 65, as he sits at 2.30 a.m. on October 18th, 1929, at the death-bed of his aged partner. The memories that flash through the less aged practitioner's mind start the story on its way; while further meditations, when he is contemplating in the morning his visits for the day, tell us something of the characters of the patients whom we are to meet. There is the impoverished old general with arterio-sclerosis and a decayed manservant as sole attendant, whose wife died in a lunatic asylum; and the ancient virgin engaged in the study of history, whose name was once connected with the general's by gossiping neighbours. She has called the doctor to see her unintelligent maid, who has got herself into trouble through a soldier in the neighbouring camp. Later in the day Dr. Serocold goes to see Mrs. Unwin, formerly married to a happy-go-lucky hunting farmer, with whom, during the lifetime of her husband, the doctor had been sorely tempted to run away. He discovers at one and the same time that she is suffering from cancer of the breast and that she has always been as much in love with him as he with her. He visits the great lady of the district, Lady Catterick, a coarse fat woman of overbearing temper, the marriage of whose son, blind and neurasthenic from the war, he encourages against the will of the mother, as the only cure. The doctor's day ends at 11.45 p.m. with the administration of an anaesthetic for his lady assistant in a difficult midwifery case. Incidentally, during the day he has attended a meeting of the town council to present his report of the health of the district; he has operated on a mastoid case at the cottage hospital; and he has gone to the house of a newly married couple to take a hand at bridge, with a view to telling the young wife about the cancer from which he has found her mother to be suffering.

Miss Ashton has described these more or less commonplace incidents with a delicate touch, and at the same time with an astonishing knowledge of medical detail and medical psychology. The doctor goes to the hospital wondering whether he is right in his diagnosis of mastoid suppuration, and whether he will acquit himself with credit in the eyes of the upstart young rival in practice who is to give the anaesthetic. The chiselling of the bone, the opening of the mastoid cells, and the feeling of triumph when a bead of pus exudes are vividly described. The reactions of the doctor's mind to the antivaccination protests of the old furniture dealer, the fiery socialism of the ferret-faced fishmonger, and the pompous self-satisfaction of the grocer-mayor, must have occurred in many another medical officer of health. And as an undercurrent

[1] *Dr. Serocold. A Page from His Day-Book*. By Helen Ashton. London: E. Byrn, Ltd. 1930. (Cr. 8vo, pp. 233 + 6d. net.)

throughout the book run self-questionings by the doctor whether the dyspeptic symptoms from which he has been suffering for some time past may not indicate that he is himself a victim of cancer. In the evening a specialist's report dissipates this fear; and the gloomy day which began with a death ends with a birth, and a ray of hope that Dr. Jean Gordon and her future husband may carry on the work of Dr. Serocold.

Where Miss Ashton acquired her intimate knowledge of the medical life we do not know; but she has effected an extremely sympathetic presentation of the daily round of the doctor. No other profession affords such wide opportunities as medicine for the study of human character. And if the romance is on a smaller scale than in some other professions, it is also more vivid and more personal. For the full enjoyment of the medical life many qualifications are necessary. Knowledge and the power of reasoning lead to good diagnosis. Intelligence is a guide to treatment. Skill and dexterity are required for good surgery. Health and energy enable the strain of practice to be borne. Courage and decision add force to action; and truth tempered with mercy is not without its advantage. But all of these gifts are comparatively valueless without sympathy, tact, and a long memory. With these three qualifications the doctor of advancing years is often able to maintain his position against the attractions of youth and modern treatment. Miss Ashton makes one of her characters say of Dr. Serocold: "You know everything about us. We don't have to explain our bodies or our minds to you. We don't need to tell you how old we are, or how poor, or how worried; you've heard it all years before. We just come to you whenever there's anything wrong; we know that you'll help us if you can, and that if there's no help, at any rate you'll understand. You've been through all our troubles with us. How can we feel the same about a stranger?"

It is probable that the best examples of the combination of these virtues are still to be found among the country general practitioners from whom Miss Ashton has drawn her hero. It is true, perhaps, that in such surroundings the liability to professional jealousy is greater; and the antipathy of Dr. Serocold towards the pushful Dr. Jevons is by no means the least interesting part of the book. It is difficult for the Serocolds to remember that some day the Jevons's will have to face the same position. In the meanwhile, the older doctor who possesses a reasonable proportion of the virtues we have enumerated will probably remain a reasonably successful practitioner. The chief fault to which he is likely to be prone is lack of appreciation of the limits of his powers.

The medical profession may well be grateful to Miss Ashton for undertaking the labour that must have been involved in gauging so accurately the thoughts and actions of a doctor, and delineating his character so sympathetically. And if the reader regrets that Dr. Serocold could not rise to heights of stoic fortitude in contemplating the approach of his own death, and that this failure casts somewhat of a gloom over his day's work, he will feel that in this matter also Luke Serocold was at least human.

C. B.

ENLARGED PROSTATE AND PROSTATECTOMY.

LECTURE BY SIR JOHN THOMSON-WALKER.

SIR JOHN THOMSON-WALKER delivered the first of his three Lettsomian Lectures before the Medical Society of London on February 17th, his general topic being "Enlarged prostate and prostatectomy." This lecture was devoted to a historical review of the subject.

Beginnings of Prostatic Surgery.

Surgical opinion with regard to operations on the prostate, said the lecturer, had undergone from time to time dramatic changes; although surgical practice had now become more settled, there were still some fundamental questions which excited differences of opinion, and certain points of surgical procedure which needed full and free discussion. The beginning of prostatic surgery as known to-day was to be found in the work of McGill of Leeds, and also in that of Bellfield of Chicago, who had died only a few months ago. At the time when McGill first attacked the subject and advocated the suprapubic operation, it was generally accepted that in a considerable proportion—estimated at about 30 per cent.—of all men over 55 the prostatic gland was of abnormally large size, but only about 50 per cent. of these had any symptoms which required attention. So long as there was no distressing micturition or partial retention it was felt that operation might be disregarded. Surgical aid was afforded by the occasional or habitual passage of the catheter, and the introduction of the coudé form was hailed by a former Lettsomian lecturer in 1880 as a great step forward in treatment. Catheter treatment was not always successful; in certain cases difficulties arose in passing the catheter, while in others the method failed owing to the frequency with which it had to be employed. Cases of acute retention at that time were dealt with in various ways. A metal catheter might be forced through the obstruction, tearing through the prostate and forming a new channel, but this was not regarded with favour by the more orthodox surgeons. In chronic cases, where intermittent introduction failed, several methods were tried, and the method of retaining a catheter for a week or more in the urethra had been highly commended by Reginald Harrison. Sir Henry Thompson, the most eminent authority at the time on surgery of the urinary organs, used suprapubic puncture as a temporary measure.

McGill's Operation.

Such was the prevailing custom when McGill first approached the subject. There had been removals of the prostate by the suprapubic route before McGill and Bellfield, but these were isolated cases, and at the time in question there was no body of opinion favourable to removal of the enlarged prostate either by the perineal or by the suprapubic route. Sir Henry Thompson, in particular, was opposed to any radical operation on the enlarged prostate. The view he held was that in cases of enlargement where the catheter failed the bladder was atonic from long disuse, and would not regain its expelling power.

On November 11th, 1887, at a meeting of the Clinical Society in London, under the presidency of Dr. Broadbent, the prospect of a discussion on the treatment of enlarged prostate drew an attendance of over eighty. Sir Henry Thompson opened by recommending permanent suprapubic drainage of the bladder as a method of treatment for advanced cases of enlarged prostate. Then Mr. McGill read a paper on suprapubic prostatectomy, and reported three cases where the operation had been successfully performed for chronic prostatic hypertrophy. He performed the operation only in cases of great urgency where catheter passing had had to be abandoned. It was not palliation, but permanent cure, which was the objective. It was interesting to notice that at that meeting Sir Henry Thompson, whose views on the uselessness of removing the obstruction were well known, joined in the discussion, expressing his interest, but reiterating his opinion with regard to the atonic bladder. He added, however, that, possibly in early cases, there was an opening for this procedure, and Mr. McGill, speaking in reply, agreed that Sir Henry Thompson was right in suggesting a period of time after which the operation would be useless.

Bellfield's Operation.

In September, 1886, Dr. W. T. Bellfield of Chicago published a short note of a case in which he performed suprapubic cystotomy for two large calculi in a case of enlarged prostate. He mentioned rather casually that the patient had collapsed so badly that no attempt was made to remove the prostatic outgrowth. The following year he was more successful. At the Chicago Medical Society, in February, 1887, Bellfield showed a man, aged 73, who had been dependent on the catheter for a year, and in whom exploration of the bladder by suprapubic incision revealed

a prostatic outgrowth as large as a hazel nut; the pedicle was twisted off with forceps and the growth removed, greatly to the patient's benefit. McGill was unaware at the time he published his first cases that Bellfield had performed this operation, but in all his subsequent papers he was careful to acknowledge his priority. The operation which Bellfield so courageously undertook, however, was a sporadic effort, which did not appear to have attracted attention, and which by itself had little influence on the general trend of surgical thought on the subject, whereas the work of McGill was an organized campaign against the prevailing views and in favour of a bolder policy.

Views on the Suprapubic Method.

McGill's conception of the anatomy of the condition he proposed to attack was set out clearly. He recognized two parts of the enlarged prostate—a part which lay within the bladder, and a part which lay outside in the normal position of the gland. The former he termed the intravesicular portion, and the latter the rectal portion, and he believed that the retention was caused by the valve-like action of the intravesicular prostate. His first three operations, from his own description, must have been rather rough-and-tumble affairs, without any definite method. He effected removal, partly by tearing with forceps and partly by cutting with scissors or with a strong cutting instrument designed for the purpose—"a tedious and not very elegant proceeding." Later, at the Leeds post-graduate course, he described his operation as consisting of two parts—the opening of the bladder and the removal of the prostatic valve—by which McGill implied the intravesicular enlargement of the prostate. Tearing with forceps and cutting with scissors were now replaced, as far as possible, by enucleation with the finger. There had been a good deal of discussion as to how much of the enlarged prostate McGill removed. It was clear that he intended to remove only the intravesicular portion. McGill did not claim that prostatectomy meant the total removal of the enlarged gland.

At the Annual Meeting of the British Medical Association at Leeds in 1889, Reginald Harrison, always a staunch supporter of McGill, opened a discussion on the subject, stating that the suprapubic operation of partial prostatectomy would occupy a permanent place in the operative surgery of this organ. In nine out of twelve cases on which McGill operated the material removed was very small, variously compared with a walnut, a bean, or a pea; but three cases were of special interest. In one of these he extracted seven pieces of enlarged prostate, the total weight being 2 ounces 30 grains; in another he removed the enlarged lateral lobe, the size of a small walnut; and in the third case the description of the specimen obtained resembled very much the prostates removed by the methods at present in use. The lecturer said that he had examined the historical specimens of enlarged prostate preserved in the museum of Leeds University, and, with that one exception, the specimens of the McGill period represented portions of the enlarged prostate, not the entire organ. Did McGill set out knowingly, in a patient obviously dying if left alone, to undertake a new and more formidable operation than he advocated in his writings? The lecturer thought not. After a careful study he did not see any evidence that McGill had changed his view that the intravesicular portion of the enlarged prostate was the cause of the obstruction he set out to treat. The removal of this obstruction was his aim. McGill had died at an early age, and there was no use in speculating what developments might have taken place had he lived to complete his work, or if his colleagues had had faith to persevere.

The first note of dissatisfaction with the operation described by McGill came from Bellfield in November, 1890. In nearly one-third of the cases of suprapubic prostatectomy which had been performed up to then he found that the radical operation failed to restore voluntary micturition. He pointed to bladder atony as the cause; but he also suggested another explanation, asserting that the discovery and removal of the outgrowths was not necessarily a complete operation. The prostatic urethra should be stretched and explored for hypertrophies with the finger and a perineal operation performed. Gouley of New York was the first surgeon to lay down a formulated plan for perineal prostatectomy.

Castration and its Effects.

In 1893 came one of those dramatic changes in the treatment of enlarged prostate which made the history of the subject so interesting. Dr. William White of Philadelphia read a paper at a meeting of the American Surgical Association on the present position of surgery of hypertrophied prostate, and at the end of an able address he put forward the idea which resulted in the almost complete banishment of prostatectomy from surgical practice for some years. He advanced a parallel between prostatic overgrowth and uterine fibroma, and suggested that castration might have the same effect in the former as ovariotomy in the latter. Castration as a method of treatment for prostatic obstruction was rapidly taken up everywhere, although prostatectomy as practised at that time was a reasonably successful operation, with a relatively low mortality. Probably opinion was influenced by the 20 per cent. of cases where the bladder did not regain power after prostatectomy, and the difficulty of the suprapubic operation probably also had its influence. For a time, therefore, the operations of castration and excision of the vas deferens held the field.

After a time, however, these indirect operations began to lose their attraction, in spite of the advocacy of many surgeons and the publication of tables of successful results. The mortality, which White had expected to be negligible, proved high, and the mutilation was such that only outstanding success would justify the operation. While in some cases improvement took place within a few days, in others months elapsed before any change could be detected. The number of cases of mental disturbance after castration was also very distressing.

Reappearance of Prostatic Surgery.

The renaissance of prostatic surgery occurred about 1900–1. Prostatectomy, by both the perineal and the suprapubic routes, found new advocates, and increased to become the routine method of dealing with prostatic obstruction. In 1901 Freyer published four cases of what he described as a new and, at first sight, formidable operation—namely, total extirpation of the enlarged prostate. The first case he dealt with in this manner was not approached with a view to performing a new operation; it was undertaken as a partial prostatectomy, and it was only after examining the tissue removed that he came to the conclusion that the whole prostate in its capsule had been taken away. Spirited discussion followed the publication of Freyer's cases, in which, out of a mass of verbiage, two mutually destructive arguments emerged—namely, that the operation performed by Freyer was the same as that advocated by McGill, and also that the operation that Freyer claimed to have performed was inevitably fatal to the patient. Mayo Robson considered that Freyer's conception of extirpating the complete prostate in its capsule involved something impracticable from the anatomical point of view, and said that, even if it were possible to take away the entire prostate, it would be inadvisable to do so. The claims of Freyer, however, aroused a new interest in the surgical anatomy of the prostate gland, and the method was taken up by surgeons all over the world.

It was a matter of comment in the early cases of operation on the prostate that bleeding was not more severe, yet in the actual cases operated by McGill, Robson, and others there were difficulties in regard to haemorrhage, and in Freyer's cases there was frequently trouble after the return of the patient to bed. On watching these cases it had become apparent to Sir John Thomson-Walker that haemorrhage, if not the direct cause of death in many cases, was a predisposing factor. Further, he recognized that stricture of the urethra following operation did occasionally occur, and sepsis after operation was rife. With these defects in mind, he introduced the method of open operation early in 1916, and afterwards used it in an increasing proportion of cases until it became his routine practice. Haemorrhage was controlled by free exposure and ligature. He was not aware until some years later that there had appeared in the papers of the Mayo Clinic an illustration showing, to quote the description, "Prostatic capsule partially closed by interrupted suture," and in 1917 there was a note published from the Mayo Clinic showing the dissection of an enlarged capsule with the bladder base exposed.

British Medical Journal.

SATURDAY, MARCH 1ST, 1930.

THE TEACHING OF ANATOMY.

A LECTURE with the challenging title "Anatomy, orthodox and heterodox," might be expected to produce some degree of tremor in an anatomist. Since the Arris and Gale lecturer this year was Mr. McAdam Eccles, most of his audience would have had some foreknowledge of the probable nature of his comments, but all must have awaited with unusual interest the considered verdict of one who has been both a teacher of anatomy and a distinguished exponent of its practical applications. It may be said at once that on the whole his verdict is extraordinarily favourable to the anatomical teaching of our own schools. Grave charges have been levelled at topographical anatomy. It has been accused of being purely descriptive and devoid of all analytical quality; a branch of study that makes no demand upon the intelligence of the learner, and from its very nature must ever remain removed from the main pathway of science; a subject, in short, whose only justification is to be found in its vocational aspect. Against such criticisms Mr. Eccles is not concerned to defend anatomy; it is for him the most concrete of sciences, except perhaps that of mathematics. He has no misgivings about its future.

So many of the medical sciences have budded off from human anatomy in the past that to some this fertility has seemed perilous, because anatomy, by surrendering to other subjects its further advances, must itself become sterile. The lecturer scents no danger here, for he sees an ever-open field for anatomy in determining the how, the why, and the wherefore of the body. It still remains a futile quest to determine whether function originates structure, or structure function; but it does seem clear that the study of structure must remain for a long time to come a fruitful form of biological inquiry. Because anatomy is so basic a subject in all medical science, and in all applications of medical science, Mr. McAdam Eccles asks whether we are getting the best out of it or not. The sister subjects of anatomy in the medical curriculum are not immune from these searchings, but critical reflections are less often heard about whether all is well with them, and whether they are playing their full part in the education of the future practitioner. It is difficult to believe that they have been let off more lightly because they are perfect. Perhaps their gradual drift from the more obvious biological field into the domains of physics and chemistry has led them beside rather than along the main high road of medicine. At any rate, they have left an abundant field of structure and function for the anatomist to explore. The anatomist seems to Mr. Eccles to be hesitant, or even reluctant, to enter on this rich inheritance. Yet in England, as elsewhere, more and more anatomists are doing such work; in more favourable circumstances it would soon be universal.

The lecturer breaks a lance with anatomical terminology and descriptive phrases. He gives examples of their occasional inaptness and, what is more serious, of misleading and erroneous language. It has been said that music and mathematics are the most characteristic creations of the human intellect; a third might be added—namely, the description of the structure of the human body, which comprises many thousands of terms that have had to be invented. A description has to be so framed that it will apply with fair precision to all human bodies, no two of which are exactly alike; it has also to be lucid and easily apprehended. The creation of this new language compares favourably with any similar attempt, and, taking it all in all, it may be confidently asserted that the innumerable labours of so many different investigators stretching over a very long period of time have produced a descriptive system that is at once useful and beautiful. As the lecturer aptly remarked, herein anatomy may claim a worthy kinship with mathematics. His second and more important contribution touched more immediately on the spirit of the teaching of anatomy. Mr. McAdam Eccles knows from his own teaching experience that the beginning of anatomy, or of any other subject, must be fraught with much dry detail and perhaps uninteresting descriptive matter. It is the necessary prelude, the unavoidable foundation that must be laid, before the process of understanding the implications of the facts can begin. When a working knowledge of the materials of the body and the conjunction of its parts has been attained, the more interesting and more fruitful computation of their significance can follow. Unfortunately, the complexity of the body is so great, and the time allotted to this study is so brief, that little more than foundation work can be attempted during preparation for the second M.B. examination. Nevertheless, the skill and insight that accrue from a knowledge of anatomy are not to be looked for as immediate results. They are the slowly ripening harvest which will be surely gathered so long as the practitioner exerts himself to maintain and extend this knowledge. The value of anatomy is best gauged by a consideration of the level at which some of its applications stand. Operative surgery, orthopaedics, and neurology at once suggest themselves, and their status is a measuring rod of the success with which the functional implications of structural anatomy are realized. Having said this much in defence of the current methods of teaching anatomy, we must agree that Mr. McAdam Eccles's observations are thoroughly sound; so cogent are they, and so in keeping with the spirit and temper of all forward-minded anatomists, that they are very welcome. Not every school of anatomy is fortunate enough to possess a complete radiological equipment, but much can be done, and is being done, to collect a variety of films for the elucidation of joint movements, bone growth, and visceral anatomy and movements. It is nearly always possible to obtain the active co-operation of the radiological department of the hospital for this work.

While the antithetical title of this Arris and Gale Lecture may cause the anatomist to approach it with some perturbation, he will find much to console him as he reads, and indeed by the end he will feel that the lecturer is a real lover of anatomy, that he has a thorough appreciation of the difficulties that beset the teacher, and a lively regard for the importance of his work. Every teacher of anatomy will heartily agree that, having laid the foundations of a knowledge of the structure of the body, it is his duty, in the interest both of the student and of his subject, to bring home the implications of that knowledge. This kind of emphasis, which will arouse the interest of the student and add life to the teaching, can be given in many ways, some of which this discourse indicates. With one of these the lecturer deals in detail. He suggests that examination questions in anatomy, and more particularly surgical anatomy, should be set in

such a way that the answers will require a good deal more than the reproduction of standard textbook descriptions; each question being so phrased as to test whether descriptive details have been merely piled up as one brick upon another, or have been envisaged in terms of function. This is certainly as desirable as it is valuable.

"PROPER AND SUFFICIENT MEDICINES."

UNDER the National Health Insurance Acts an insured person, as part of his medical benefit, is entitled to receive "proper and sufficient medicines." This phrase includes such chemical reagents as may be authorized by Regulations. Under his terms of service an insurance practitioner is required himself to supply to an insured patient "drugs" in certain circumstances, and here the term "drugs" is defined so as to include "medicines." In any case, these drugs or medicines must be only those which are "requisite for the treatment of the patient," and the cost must not be in excess of "what is reasonably necessary for adequate treatment." Such articles as foods, toilet preparations, and disinfectants, as such, are clearly outside this category; but questions as to the propriety of supplying or prescribing numerous articles have from time to time been raised, and a year ago the Minister of Health appointed an Advisory Committee on the Definition of Drugs for the Purposes of Medical Benefit. This committee has presented two reports on the matters referred to it, and these have now been circulated by the Ministry to Insurance and Panel and Pharmaceutical Committees.[1] In the first report the committee suggests a new Regulation defining the procedure to be adopted when a medical practitioner has ordered, or is alleged to have ordered, on the official prescription form, any "substance or article" which is not a "drug or medicine." In the second report the committee classifies 165 substances and preparations which have been referred to it into those which are never drugs, those which are always drugs, and those which are sometimes drugs. Articles in the last two classes are subdivided into non-proprietary and proprietary. These last, again, may be of known composition or may be of a composition which is undisclosed. The committee considers that in the former case "an insurance practitioner might reasonably be called upon to justify the prescribing" of them; and in the case of the latter says, "the prescribing of such substances and preparations is most undesirable; only the most exceptional circumstances could justify a practitioner in prescribing them." Of course, the classification of these substances by the Advisory Committee is not final. The decision as to allowance or disallowance rests primarily with Insurance Committees, and the decision in any particular case could be challenged in a court of law. Nevertheless, these reports will be of value to those committees, as well as to insurance practitioners and pharmacists.

In each report there is one important matter which calls for further comment. In explaining the effect of the suggested Regulation the Advisory Committee says: "The insured person would have the right of complaint against the insurance practitioner under Article 32 of the Medical Benefit Regulations, 1928, for refusing to prescribe an alleged drug." This, as phrased, is dangerous doctrine. The statement may perhaps be justified in the narrowest sense by the fact that Article 32 says that "Any question arising between an insurance practitioner and a person . . . entitled to obtain treatment from that practitioner . . . shall be investigated by the Medical Service Sub-committee." But if (as the committee now appears to lay down) "any question" is to be regarded as including the right of a patient to have given to him, or prescribed for him, the drug or preparation which he thinks he ought to have, irrespective of whether the practitioner thinks it appropriate or not, the medical profession could not for a moment countenance the right of an insured person to raise any such question. The word "refusing" seems to imply a "demanding" on the part of the patient. It would be a topsy-turvy kind of medical practice in which the patient named the drug and the doctor obediently prescribed it, or, greatly daring, declined to do so.

The position with regard to the ordering of cod-liver oil, extract of malt, and preparations of these substances is dealt with in the second report of the committee. It is by no means free from difficulty. This has been emphasized by a recent case which has attracted public notice. A partnership of doctors of the highest reputation, practising in one of the poorest parts of London, has had a considerable sum deducted from the amount payable to it by the London Insurance Committee on the ground of "excessive prescribing," particularly with regard to cod-liver oil and malt. The practitioners maintained that this was required owing to the poor state of nutrition of a number of their patients. It is unquestionably desirable on medical grounds that any undernourished person should be supplied with further nourishment. The State has, however, established means by which, in approved cases, alimentary needs can be supplied; and even if communal action does not go far enough in this direction, there are plain reasons why such deficiencies should not in general be made good at the cost of a fund established for therapeutic purposes. Any other course might be held to justify the ordering of loaves of bread or pounds of butter or pints of milk for necessitous patients at the expense of the Drug Fund. Medical considerations alone should decide in each case whether cod-liver oil and malt extract are to be regarded as food or as drugs. The Advisory Committee on the Definition of Drugs, after weighing the arguments, reaches the cautious conclusion that these substances "are occasionally prescribed in circumstances which render it difficult to establish that their use was therapeutic rather than alimentary"; or, in other words, that malt and oil "may be, but are not always, drugs or medicines for the purposes of medical benefit."

[1] H.M. Stationery Office. 1929. 3283 and 3292.

A CUMBERLAND MATERNITY SCHEME.

THE health department of the Cumberland County Council has issued a pamphlet by Dr. F. H. Morison, the county medical officer of health, which is entitled a "Report on a complete scheme of maternity and child welfare." It is an admirable document, which sets forth fully for the benefit of the members of the health committee of the county council and of the council itself what is at present being done in Cumberland, both for mother and for infant, what remains to be done, and the way in which it is suggested that this should be done. Every attention that can lawfully be given during the ante-natal, natal, and post-natal periods, and by way of infant and child welfare work during the last of these periods and thereafter, is duly considered, and the detailed needs of the county in respect of its various areas or parishes are presented for attention. The various agencies—the private doctor, the specialist, the midwife, the home visitor, the nurse, the infant welfare centre—are placed in their proper relationship to one another and to the scheme as a whole. The

scheme emphasizes the use of the private medical practitioner as the main prop of any systematic arrangements, with the midwife as his constant help, and the centre as an invaluable educative agency in respect of both maternity and mothercraft. The maternity hospital provision of the county is reviewed, and while Dr. Morison recognizes that some further provision is required, he states clearly that its proper use is for abnormal cases, and that "for normal cases in which the home accommodation is quite unsuitable the problem is a different one. These are in no sense emergency cases and therefore, except for sentimental reasons, it is not necessary, nor is it possible, except at enormous expense, to have accommodation in all thickly populated areas." In fact, the scheme is based upon the principles which underlie the national scheme of the British Medical Association, and the arrangements, so far as they can be provided and carried out by a local government authority, are similar to, and perhaps also based upon, those suggested in that scheme. It is useful to know that they can be applied, practically *in toto* and without serious modification, even to the peculiarly difficult conditions which exist in a county like Cumberland. It is possible that the medical officers or health departments of some other counties have prepared similar schemes and set them out in documents; in any case this small publication from Cumberland may be worth their attention. The estimates of cost appear on the whole to be rather liberal: if this be so perhaps it is a good fault. There is, however, just one paragraph that cannot be commended: even if true the situation might probably have been dealt with in a better way. Speaking of the use of untrained and uncertified women in connexion with confinements, Dr. Morison says, "I have grounds for believing that certain of these handy women habitually attend confinements, and unfortunately are 'covered' in their illegal activities by some medical practitioners." This is a very serious accusation to make: if proved, it would almost inevitably result in the practitioners' names being removed from the *Medical Register*. It must be remembered that there is nothing ethically wrong in the use of such women as maternity nurses in cases where a doctor is also in attendance. It may be that this is the practice which Dr. Morison views with strong disapproval: if so, he will generally be held to be correct. This, however, is a different matter, and the propriety of the use of a woman in this particular way depends upon the availability or otherwise of certified midwives, the personality and experience of the woman, and the fullness of the responsibility accepted and the actual attention given by the doctor.

THE MONASTIC INFIRMARIES.

THE infirmary of the mediaeval monastery, with special reference to the Abbey of Westminster, was the subject of a lantern lecture delivered by Mr. Percy Flemming, emeritus professor of ophthalmic medicine and surgery, at University College, London, on February 21st. The lecturer stated that there was no infirmary belonging to a monastery in this country standing at the present time; all that remained were some well-preserved ruins. But it was possible to reconstruct in the imagination the character of the monastic infirmary in the Middle Ages, and from the ruins of Furness Abbey in particular a great deal was to be learnt with regard to the domestic offices of the monks. Generally speaking, the west end of a monastery was used for business purposes, and the east cloister was the site of the infirmary. Those who designed the monasteries were not unfamiliar with the principles of sanitation, and much thought was given to the lay-out and slope of the ground with a view to drainage. Attached to the monastery was always a garden devoted to the growing of herbs for medicinal purposes. Coming to Westminster Abbey, Mr. Flemming drew attention to the fourteenth century door in the middle of the east wall in the Little Cloisters; this, he said, was the door of the infirmary chapel, rebuilt after a fire. Incidentally, a very common ailment among the monks was disease of the shin bone, possibly brought about through much kneeling at a time before hassocks were available. It might easily have originated as a small abrasion, and as baths were very infrequent—at Westminster the allowance of baths was only two a year—possibly the neglected abrasion developed into more serious trouble. It was recorded at Westminster that in 1310 one monk had the trouble in both legs, and another entry, under the date 1334, stated that a monk had surgical treatment for it at a total cost of forty-six shillings. Bleeding was a common form of treatment; there was always a group of people in the monastic infirmary who had recently been bled. Even apart from any illness, there was periodic bleeding in those days, and after it a certain amount of relaxation was allowed to the monks. The records seemed to show that they had a good time in the infirmary, and were anxious rather than otherwise to be bled, even more often than was necessary. The Dean of Westminster, who presided at the lecture, spoke in appreciative terms of the perfection of the arrangements of the modern hospital, and the blessings which scientific medicine and surgery had brought. The difference between the treatment now available to the poorest and that which was given in the old times in the monastic infirmary was so immense that the two things could hardly be spoken of in the same breath. He added that at Westminster Abbey the infirmary was used for various purposes, not limited to the care of the sick or the convalescent. It was there that the young monks were regularly whipped, the idea apparently being that the place where health was restored to the body was the best place for correcting the soul. It was in the infirmary also that the "playfellows" were housed. These were monks of over fifty years' standing, who were constituted censors of everything that went on in the monastery. It might be imagined, said Dr. Foxley Norris, how nice a state of things existed when a party of playfellows—a most inappropriate name—lived at their ease in the best quarter of the monastery, their only occupation being to criticize the others. But the debt of medical science to the monasteries must not be forgotten. The monasteries were at the beginning of nearly everything. Whatever poor relief was distributed in those days came through the monastic infirmary. The history of England on the social side might be described as the gradual taking over by the public authority of what in its origin was voluntary and vouchsafed in the name of religion. But he trusted that the day was far distant when the voluntary hospital, which represented the spirit of the old monastic infirmary, but represented also the best that modern science and skill could command, crossed the same Rubicon.

HUGH OWEN THOMAS.

SOME sixteen months ago we welcomed the conversion of *The Cripples' Journal* into *The Cripple*, and commented on the intention of that journal in future to include in its scope crippling in the widest sense of the term, such as the effects of rheumatic heart disease and chronic arthritis. The current number, for February, 1930, is now before us, and we much regret to read in the editorial notes an announcement that this is to be the penultimate issue, for it has been decided, owing to several urgent considerations, to stop publication with the April issue. The editor promises in the concluding number a historical survey of the work for the cripple in its origins and development. Although naturally disappointed by the necessity for cessation of publication, he is prepared to go down with his flag

flying, believing, as he evidently does, that other hands will yet bear it aloft in triumph. "Six years ago," he writes, "the struggle was principally directed towards the discovery and treatment of the crippled child. To-day we are on the eve of a great effort to provide training and employment for the man or woman disabled from their normal occupation, or deprived of proper opportunities in adolescence." It is fortunate that the seventh of the series of articles on pioneers of orthopaedics by Mr. Arthur Rocyn Jones has appeared in this number before *The Cripple* comes to an untimely end, for its subject is "Hugh Owen Thomas"; this excellent and most interesting account by Mr. Rocyn Jones can be recommended to the growing number of readers who are interested in the history of medicine. Thomas was a man of an unconventional turn of mind, of great originality, and dogged industry and perseverance. Had it not been for the obscurity in which he liked to work, and to the imperfect way in which his views were expressed and put before the medical public, he must have enjoyed during his lifetime some at least of the fame which is now attached to his memory. He sought no academic honours or hospital appointments, but was content with a single qualification, which would nowadays not entitle him to practise midwifery or medicine and pharmacy. Probably circumstances compelled him to earn a living in general practice, if he did not deliberately choose that way of life. In his daily work among a large industrial population he learned lessons which he turned to good account, and he introduced into his practice the ideas of his shrewd and active brain as actual procedures. Others before him had preached rest in joint disease; he was the first to show how it could be attained in practice, with simple means and at small expense, by any practitioner sufficiently mechanically minded to learn the lessons given by Thomas. His books were little read, however, for he was not well advised in his methods of bringing them before the medical public, and he had not an attractive literary style. Moreover, it must be confessed that the "dons" of the medical world were little inclined to listen to a provincial practitioner who not only supplied, but actually made and fitted, instruments for his patients with his own hands. Was it not notorious that his father, with whom he had worked in Liverpool, was a bone-setter? It is scarcely to be wondered at that some seventy years ago, when the Medical Act was yet new, and unqualified practice was becoming or had become disreputable, the taint of bone-setting was enough to cause a prejudice which reacted unfavourably on the reputation of Hugh Owen Thomas among the majority of his contemporaries, although there were men of wider views, such as Sir John Erichsen, who recognized the brilliant quality of the diamond in its somewhat uncouth setting. Thomas's splints and Thomas's methods are to-day household words of surgery throughout the British Empire and the United States, but we are bound to add regretfully that there is scant mention of him or his work to be found in orthopaedic or general surgical works published on the continent of Europe.

CONTROL OF MALARIA

THE eight or nine hundred pages of volume ii of the *Transactions* of the 1927 Far Eastern Congress of Tropical Medicine[1] are full of matter, much of it displayed elsewhere before and since, and some of it worthy of this repeated publication. It is obviously fitting that malaria should occupy much of the time of congresses on tropical medicine; here it receives over 250 pages, from which there might be omitted, with advantage, twenty-six which end with the conclusion that "smalarina" is useless for the treatment and prevention of malaria. These congress reports threaten to become impossibly bulky, and we venture to say that long before 1927 no one had any remaining faith in "smalarina" save those whose faith is definable as belief in what is known to be incorrect. The discussion on control of malaria must have been particularly interesting, for it brought together (and at times almost into conflict) those belonging to what Professor Stephens nicknamed the "wet" and "dry" schools of thought, the former placing chief reliance on antilarval measures, and the latter inclining rather (at least in the first place) to other measures as set out in a recent League of Nations report. The former side does, indeed, seem to show some unwillingness to abandon the belief that all sound antimalarial work *must* be founded on antilarval measures. Further, there is some carelessness in attributing sole or major credit to the antilarval measures when other action has played a part. For example, Strickland says (p. 64) that the Panama Canal operations are an example of antimalarial work "based on" ascertainment of the local anopheles and dealing with it "in the breeding places alone." This belief is common, but Chamberlain,[2] the chief health officer of the Canal Zone, has put it on record that the antimalarial measures in Panama were as follows: "First, an attack against the malarial parasite itself in the human body by means of vigorous treatment. . . . Second, an attack against adult mosquitos . . . by cutting away . . . underbrush, screening houses, and systematically killing the insects in dwellings." Only third came antilarval measures. As we go to press the third volume of these immense *Transactions* reaches us. The editor, Lieut.-Colonel J. Cunningham, who also acted as organizing secretary of the congress, must feel thankful that his heavy task has now come to an end. The general production of the work reflects much credit upon him and upon the publishers.

QUAKERS IN SCIENCE AND MEDICINE.

THE results of religious persecution have seldom fulfilled the expectations of its promoters. Quite commonly it has served to secure the material advantage of the persecuted, and when it has secured their spiritual advantage too—perhaps the most usual effect of persecution on the persecuted—it has never done so quite in the way that was intended. The Quakers, for example, were debarred in the past from universities, the fighting services, law, divinity, and other forms of activity, and were thus able to concentrate on business, the study of nature, and charity. A small body—ten years ago the Society of Friends had a membership of only 19,000—they have produced men and women eminent in almost every walk of life. Certainly they have been remarkably successful in banking, brewing, and chocolate making, to go no further down the alphabet; and while their shrewd sense has enabled them to make money, their religious convictions have impelled them to give it away, and they have been responsible for originating many of the great philanthropic movements in the last century. In his volume of essays *Common Sense and its Cultivation*, published three or four years ago, Dr. Hanbury Hankin showed, by taking the figures of membership of the Royal Society between the years 1851 and 1900, and estimating what proportion were of Quaker stock or descent, that a man had about forty-six times as much chance of being elected a Fellow of the Royal Society if he was a Quaker or of Quaker descent as he had if he belonged to the rest of the nation. Going on to what may perhaps seem an optimistic prophecy, he argued that as the rate of election of Quaker Fellows is rapidly increasing, whereas that of non-Quakers is rapidly diminishing, the Royal Society will at no distant date become a branch of

the Society of Friends! Sir George Newman (who has written so charmingly in *The Friend* and elsewhere about George Fox and his followers), in the course of the Lister Lecture on the application of Quaker principles to medicine, which he delivered before the Quaker Medical Society on October 17th last, expressed the view that it was the Quakers' scientific study of nature and their innate public spirit that made an unusual number of their community turn to the profession of St. Luke, or to its allied branches of the sciences. George Fox (1624–1691) was tempted to "practise physic for the good of mankind," and desired that part of the Philadelphia property given to him by William Penn should be devoted to a "physic garden." From that time on there has been a constant succession of Quaker medical men of eminence, such as Richard Lower of Oxford (eponymous in the "tubercle of Lower"), who performed blood transfusion on dogs in 1665; the famous John Fothergill and his disciple John Lettsom; Thomas Dimsdale, "the inoculator"; the remarkable trio, Thomas Young, Thomas Hodgkin, and James Cowles Prichard, author of *The Physical History of Man*; and, within the memory of many, Jonathan Hutchinson and Lord Lister. There are many others, not so well known, who have served their day and generation well on account of their Quaker principles and character.

STATE INSURANCE AND TRAUMATIC NEUROSES.

THE great increase in the opportunities for the study of traumatic neuroses which occurred as a result of the war dispelled all doubt as to the purely psychical nature of these conditions. It has, in consequence, become possible to lay down uniform rules of treatment and prophylaxis, and to estimate the capacity for work in soldiers suffering from nervous symptoms. On the other hand, the causal connexion of nervous symptoms with war work has not been very closely studied, and the Ministry of Labour in Germany has, accordingly, invited a number of neurologists to express their opinion on certain points bearing more especially on questions of State insurance. The opinions were given in the form of a series of lectures, which have been collected into a single volume.[1] The contributors were Dr. Leppmann, Minister of Health, Professors Hoche, Stier, and Wilmans, Dr. Kronfeld, Dr. Jossmann, and, as representing the law, Dr. Knoll; a general review of the whole was undertaken by Professors Weiler and Stern. Answers to certain specific questions were asked for, and the general results of the investigation may be gathered from a circular of instructions based on the results, which has been issued to the insurance authorities throughout Germany. In this it is directed that as difficulties in diagnosis at times arise, and special circumstances sometimes influence the decision, it is important that anything in the nature of routine methods of dealing with cases should be avoided. The circumstances of each individual case should be carefully inquired into. With regard to the question how far the existence of a neurosis indicates a psychopathic disposition, it is admitted that it might do so in individual cases; the authorities are, however, relieved from following up that line of inquiry, and the custom of entering cases as of "psychopathic or neuropathic disposition" is directed to be discontinued. Cases in which neurotic symptoms appear for the first time years after an external injury are not to be held entitled to indemnification. Cases in which there is a renewal of neurotic symptoms, of a similar or different character, after a prolonged period of total or almost total freedom from symptoms, are not to be held entitled to indemnification. Cases in which a sudden aggravation of symptoms occurs after a stationary condition lasting for years are not to be held entitled to indemnification. In the application of these rules, however, rule-of-thumb methods are to be avoided, and the possibility of a connexion between the patient's symptoms and his work must be carefully considered. Where the long duration of symptoms suggests, in accordance with scientific experience, that the symptoms are not related to the alleged injury, the indemnification is not to be revised unless it can be proved that the symptoms are definitely referable to some other cause. These rules, it should be noted, apply only to cases in which there is no organic lesion.

SHIP CAPTAIN'S MEDICAL GUIDE.

A NEW edition of *The Ship Captain's Medical Guide*,[1] edited by Dr. D. D. F. Macintyre, surgeon commander R.N.V.R., medical inspector of the Board of Trade, has recently made its appearance. This is the seventeenth edition of a book the foundations of which were compiled many years ago by the late Dr. Harry Leach, medical officer of health for the Port of London. It represents a considerable advance on its predecessors, and contains much new material. The medical scales for merchant ships which are not required to carry surgeons have been brought up to date with the help of experts nominated by the Ministry of Health and shipowners' associations. Of peculiar interest to us and our readers is chapter 23, which deals with requests by wireless for medical advice. This is based on the work of a special committee set up by the Council of the British Medical Association. That committee drew up a case-taking scheme, which was designed to secure that the master of a ship not carrying a surgeon, who wanted to send a wireless message for medical advice to the shore or to a ship carrying a surgeon, would be able to state quite categorically and in proper sequence all the essential information about the patient that the surgeon would require in order to enable him to send the necessary advice without having to waste time in asking supplementary questions. The system has been adopted in its entirety, and is capable of easy transmission into code. If, as is quite possible, the coded system is adopted by the Washington Conference and incorporated into the International Code of Signals, it will enable the master of a ship of any nationality to get all the advice he requires from any ship carrying a surgeon which may be within wireless range.

INDUSTRIAL PULMONARY DISEASE.

THE Medical Research Council has appointed a committee to advise upon the further investigation of pulmonary silicosis and of other pulmonary conditions associated with the inhalation of dusts arising from industrial processes. The chairman is Professor Arthur J. Hall of Sheffield, and the other members are Dr. A. E. Barclay, lecturer in radiology in the University of Cambridge, Dr. J. C. Bridge, Senior Medical Inspector of Factories, Home Office, Professor S. Lyle Cummins, director of research to the Welsh National Memorial Association, Professor E. H. Kettle, St. Bartholomew's Hospital and College, Professor M. J. Stewart of Leeds, Dr. Cecil Wall, physician to the London Hospital and the Brompton Hospital, and Dr. E. L. Middleton, Medical Inspector of Factories, Home Office (secretary). The committee will survey the present state of knowledge, will advise the Council upon new lines of inquiry that may be profitably pursued, and will assist in the supervision of such investigations as it may be decided to initiate or support. The work will be directed particularly towards obtaining, in co-operation with the Factory Department of the Home Office, more accurate knowledge of the causes and diagnosis of silicosis and of other indus-

trial pulmonary disorders. The need for better knowledge of these subjects has been emphasized by the recent report of the Silicosis (Medical Arrangements) Committee, whose recommendations to the Secretary of State for extended research work have been referred to the Council by the Home Office.

WE have to announce with much regret the death, after a brief illness, of Sir Alfred Fripp, K.C.V.O., Honorary Surgeon to the King and consulting surgeon to Guy's Hospital. An obituary notice, with portrait, will appear in our next issue.

THE annual general meeting of the Royal Medical Benevolent Fund will be held at 11, Chandos Street, W.1, on Monday, March 10th, at 5 p.m. The annual report and financial statement for the year 1929 will be presented, and the officers and committee elected for the current year.

THE Minister of Health has appointed Sir Harry Goschen, Bt., to be a member of the Board of Management of the London School of Hygiene and Tropical Medicine, in the place of Lord Melchett, whose term of office recently expired, and the Board has elected Sir Harry Goschen as its chairman, in succession to Lord Melchett.

AMONG the fifteen candidates recommended by the Council of the Royal Society on February 20th for election into the society are John Stephenson, D.Sc., F.R.C.S., Lieutenant-Colonel I.M.S. (ret.); Charles Todd, M.D., attached to the Department of Experimental Pathology of the National Institute for Medical Research; William Whiteman Carlton Topley, M.D., F.R.C.P., professor of bacteriology and immunology in the University of London; H. W. Dudley, M.Sc., Ph.D., of the biochemical and pharmacological staff of the National Institute for Medical Research; and Robert Robison, D.Sc., of the Department of Biochemistry, Lister Institute.

RED CROSS CLINIC FOR RHEUMATISM.

NEW BUILDING AT REGENT'S PARK OPENED BY THE QUEEN.

By the release of a valve thereby filling a large bathing pool, Her Majesty the Queen on Tuesday last opened the new Red Cross clinic for the treatment of rheumatism. The clinic is situated at the gates of Regent's Park, in Park Square East, in a building adapted from the old Baptist chapel there, which had stood derelict for some seven years. The octagonal shape of the interior is preserved in the new arrangement, and where formerly the baptistry stood there is now another Siloam, a central deep pool for manipulation, exercises, and under-water douches.

As has already been set forth in these columns,[1] the British Red Cross Society was approached on the one hand by representatives of the approved societies, and on the other by members of the medical profession interested in balneology, with a view to launching an appeal for funds to establish and equip a demonstration clinic in London where insured workers and others could obtain physical treatment for the diseases classed as rheumatic. An appeal for £40,000 was made, and when about two-thirds of this sum had been subscribed Sir Otto Beit generously guaranteed the remainder.

A first impression of the clinic is wholly pleasing. On the ground floor in the centre of the building, and open to the high glass roof, is the central deep pool. The colour scheme of the tiling is arranged after the manner at spas; indeed, acknowledgement is made of the help in many directions, by suggestion and advice, which British and Continental spa experience has afforded. Around this pool, under arches, are ample dressing and rest accommodation, and separate apartments providing for shower and foot baths, reclining and aeration baths, a whirlpool bath, and a Scottish douche, appliances for giving douche massage on the Vichy and Aix systems, and hot air and vapour applications. On the first floor, where the rooms are again arranged in gallery fashion around the well of the building, are rooms for treatment by massage and movement, radiant and non-radiant heat, and ultra-violet radiation, also a room for colonic lavage (Plombières treatment), and consulting rooms. The top floor, connected with the others by lifts, is arranged for the treatment of private patients—that is, patients who do not receive the treatment as an additional benefit through their approved societies—by all the methods in use on the lower floors.

The conditions to be treated at the clinic are set out as chronic rheumatic diseases, articular and non-articular; muscular weakness or paralysis, neuritis, and neuralgia; and sequelae of injury to or inflammation of joints, muscles, tendons, bones, and nerves. The fee for the approved society patients will be, as an experiment, 25s. for a course of not less than eight treatments. Fees for private patients will be by arrangement with the lady almoner. Sir Arthur Stanley said that it was hoped to treat a certain number of necessitous cases free. It is considered that the clinic will be available for the treatment of between three hundred and four hundred patients a day, and to accommodate its working-class patients it is intended to keep it open until nine o'clock on three evenings a week. Arrangements have been made with the neighbouring Royal National Orthopaedic Hospital for the treatment of cases which require the help of an orthopaedic surgeon, and the hospital is also undertaking for the present to do all the *x*-ray diagnosis work for the clinic.

In addition to a number of distinguished honorary consulting physicians, the staff consists of five honorary medical visitors (Drs. W. C. S. Copeman, C. B. Heald, F. D. Howitt, B. S. Nisse, and M. B. Ray), the medical superintendent (Dr. A. R. Neligan), and the sister-in-charge (Miss McAllister). Those concerned in the management of the clinic are anxious to make it plain that its services are not limited to insured patients, but that other persons may obtain treatment on the recommendation of their practitioner, also that the clinic is open to both London and provincial patients. It is hoped that it will be the centre of a group of clinics throughout the country, especially in industrial districts. There are between thirty and forty Red Cross clinics in existence, though not specifically devoted to the treatment of rheumatism; two noteworthy ones in London are at Kensington and Hackney, which serve large districts. It is expected that these Red Cross clinics will serve as receiving stations for the central clinic at Regent's Park, and will integrate their work with it. The hope has also been expressed by Sir Arthur Stanley, chairman of the Executive Committee, that this new establishment may be a centre of research on the problem of chronic rheumatism, as well as a place where the industrial invalidity from this cause may be ameliorated.

Opening Ceremony

At the opening ceremony the Queen, who was accompanied by the Duke of York and the Chairman of Council of the British Red Cross Society, received an address in which the origin and purpose of the clinic were described. The address, which was read by Brigadier-General H. B. CHAMPAIN, referred to the substantial assistance which had been received from the friendly and approved societies, and to the fact that the Minister of Health had added the treatment of rheumatism to the insurance benefits for which payment might be made by the societies in respect to their members receiving treatment. The clinic formed part of a national movement to deal with the problem of chronic rheumatism.

Mr. ARTHUR GREENWOOD, Minister of Health, in thanking Her Majesty, said that at least £5,000,000 was paid out each year in health insurance and disablement benefit to people suffering from rheumatism, and adding to that the amount of wages lost each year the cost of the disease annually was at least £17,000,000.

Canada.

The C.M.A. Journal.

THE January issue of the *Canadian Medical Association Journal* opens with a foreword signed by Dr. A. G. Nicholls, who (as already mentioned in these pages) has succeeded Dr. A. D. Blackader in the editorship. This statement of policy declares that the same principles which have moulded the journal in the past and have proved so successful and will continue to shape it in the future. "Stated broadly, it is the desire of the editorial staff to make the journal thoroughly representative of the best in Canadian medicine, and to make that best known beyond our own borders." Two further passages from the same editorial article may well be quoted here.

"The general practitioner of the present day is well trained, alert, and often well read. In these days of rapid transit he can easily and quickly get in touch with medical centres. If he cannot leave his practice for a sufficient length to engage in post-graduate study, the latest in medical thought is brought to his door, or to his next door, by his magazines and post-graduate lecturers. In our opinion the general practitioner can appreciate the best that medical journalism can give him, and is entitled to it. He should hear of any new clinical experience, of any advance in research, of any new discovery in medicine."

"Besides the substance of a journal there are other matters to be considered. For instance, there is its style and language. Without intending to be purists, the editors desire the *Canadian Medical Association Journal* to be couched in pure, simple, and correct English. Some standards must, of course, be followed. Our standards are the *New Oxford Dictionary* and Fowler's *Modern English Usage*. Contributors will understand that when alterations are made in their manuscripts this is not done in any captious spirit, but solely with the desire of bringing their language into conformity with the best accepted English models. Our journal is published in the English language, in a British country; our desire is to make it the exponent of all that is best in Canadian medical thought, to maintain for it a worthy place among the journals of the Empire, and to exemplify in it the best that is in the British tradition."

Liability of Nurses to Tuberculosis.

The incidence of tuberculosis among nurses is the subject of an essay by Dr. E. L. Ross, for which he has been awarded a prize of 250 dollars by the Canadian Tuberculosis Association. This is one of two prizes offered annually by that association for papers recording the results of studies in tuberculosis, either the laboratory or clinical phases. Competition for the prizes, which are open to all sanatorium physicians of less than five years' standing, has not so far been very vigorous, and Dr. D. A. Stewart, president of the association, himself a prolific and stimulating writer, has issued a kind of open letter to all superintendents of sanatoriums in Canada, urging them to induce their staffs to produce more papers on tuberculosis. Advantage, he suggests, should be taken of the long winter months. Dr. Ross states that sixty nurses were admitted to his sanatorium in Manitoba during the past five years; this number is far above the average, and is also more than the proportion of girls of their average age. With very few exceptions these nurses broke down during their training in general hospitals, or during the first year after their graduation, while still on the staffs of general hospitals. This frequency of tuberculous infection can be partly explained, he thinks, by the early age at which nurses begin their training, their previous freedom from contact with the disease, and their being unaccustomed to hard work. He suggests that girls should not be accepted until they are 21, and that there should be better regulation of their hours of work. They should undergo a thorough physical examination at the commencement of their training, and *x*-ray photographs should be taken of their lungs. He also emphasizes the fact that a nurse in a general hospital is too often exposed to chances of infection from patients who may be there for some condition other than tuberculosis, but who at the same time may have open pulmonary disease. In such circumstances the nurse is not advised to take the necessary precautions which are sufficient, apparently, to reduce the incidence of tuberculosis among those in sanatoriums.

The High Cost of Nursing.

The Association of Registered Nurses in the Province of Quebec recently decided to raise the scale of charges for ordinary nursing. The rate, from 1930, is increased from 5 to 6 dollars a day, excluding cost of meals. This step has been taken only after prolonged and careful consideration of the problems associated with modern nursing. Apart from remuneration, committees have also been engaged in studying other economic questions. Is there a growing demand for the partially trained attendant in preference to the fully trained nurse? Does the supply of trained nurses exceed the demand? Should the training of nurses be limited to hospitals containing more than 100 beds, or to those with more than 200 beds? How much didactic and laboratory teaching is required for training a nurse? What requirements should be demanded from candidates? There is little doubt that the expenditure on medical care is becoming so heavy that nursing is being regarded rather critically by the layman, but it can be shown that even with the increased remuneration a nurse's income will still be inadequate, taking into account the unavoidable loss of time in actual nursing, constant overhead expenses, and the risk of frequent breaking down in health. To raise the fee is apparently only a temporary expedient: the real solution of the problem is to provide steady employment, so that fees may be adjusted to a lower level. A day nurse and a night nurse, with their meals, cost 16.50 dollars per full day. It is not surprising, therefore, that there is an increasing demand for partly trained attendants, who, however, are not permitted to nurse in the larger hospitals of the city. In home nursing and during convalescence they often help to solve a difficult problem.

Ontario Medical Association.

The Ontario Medical Association, which was founded in 1880 and now has a membership of 2,000, will hold its jubilee meeting in Toronto on May 27th, 28th, 29th, and 30th of this year, under the presidency of Dr. John Ferguson, associate professor of clinical medicine in the University of Toronto, who is a charter member of the association.

Scotland.

Edinburgh Rheumatic Clinic.

DR. WILLIAM ROBERTSON, medical officer of health for Edinburgh, on the authority of the Public Health Committee, has issued a circular to medical practitioners announcing a system of voluntary notification of rheumatism. The circular also states that it has been agreed to establish a Rheumatic (Supervisory) Clinic, to which those suffering from rheumatism, chorea, growing pains associated with temperature, and acquired cardiac disease may be submitted for examination. The clinic will be held every Wednesday at Spittal Street Dispensary, at 4.30 p.m., and will be supervised in rotation by Dr. Charles McNeil, Dr. Norman Carmichael, and Dr. Lewis Thatcher, visiting physicians to the Royal Hospital for Sick Children. Its objects are: to verify the notified cases referred to the clinic; to grade the patients according to their disability; to keep them under periodic supervision, provided the medical practitioner in charge consents to this; to refer those requiring treatment to their private attendant or to the hospital where they have been previously under treatment; and to estimate the existing facilities for such treatment. The clinic is not expected to undertake treatment. A fee of 2s. 6d. will be paid for each notification, which will include the patient's name, age, address, and the phase of rheumatism.

Edinburgh Royal Medical Society.

The annual dinner of the Royal Medical Society of Edinburgh was held in the Royal College of Surgeons on February 20th, under the presidency of Dr. A. G. G. Melville; the guest of the evening was Dr. J. Haig Ferguson, President of the Royal College of Surgeons. In replying to the toast of "The Imperial Forces," Rear-Admiral Hallett referred to the services which doctors had

rendered to the navy during his lifetime in eliminating Malta fever. No one died from Malta fever to-day. Colonel P. S. Lelean, replying for the army, spoke favourably of the recent appointment of a physical training director in Edinburgh University. In proposing "The Royal Medical Society," Dr. Haig Ferguson said that the Freemasonry of this society had always united its members. Goldsmith, who had joined it in 1752, described a society, which may have been the Royal Medical Society, in the following words: "Happy society, where the members think before they speak, deliver nothing rashly, but convey their thoughts to each other pregnant with meaning and matured by reflection." He advised every medical student to become a member. Dr. A. F. K. Clarkson, in reply, referred to the bicentenary of the society, which would be celebrated in 1937. He thought that everyone who had benefited from the Society should contribute to the bicentenary fund, which would be used for the improvement and preservation of the Society's library. In acknowledging the toast of "The University of Edinburgh," Sir Thomas Holland, the Principal, said that the Royal Medical Society had made great contributions to the success of the Edinburgh Medical Faculty, and the Royal Infirmary had made the science of medicine a living science. Edinburgh had been the foremost school of medicine in the world for two centuries. As Principal he intended to encourage its research work, for which it was already famous.

Cancer Treatment in Glasgow.

A meeting was held in Glasgow on February 19th for the formation of a Ladies' Auxiliary for the Glasgow and West of Scotland Radium Institute. Professor J. H. Teacher, who presided, said that it was generally agreed that radium was a most important treatment for certain types of cancer. The Radium Institute in Glasgow was well equipped and staffed, and was the only institute of the kind which was in full operation. Dr. R. R. Morrison discussed different methods of radium treatment and the difficulties in the manipulation of radium for application to different parts of the body. Dr. F. L. Henderson referred to the use of x rays, and exhibited one of the first x-ray tubes that had been used, having been sent by the discoverer of x rays to the late Dr. John M'Intyre of Glasgow, who was a pioneer in this work. One of the great difficulties of x-ray departments was the expense of keeping x-ray apparatus up to date, for this apparatus probably went out of date every five years. The useful form of radiation treatment that was being done in this country and abroad at the present time was a combination of treatment by x rays and radium. Dr. Edington said that one of the objects in founding the Radium Institute was to form a central depot or department from which radium might be lent to other institutions, and another object was the training of medical men in the handling and use of this very important remedy. A gift of £10,000 from Lady Burrell had enabled them to inaugurate the institute, but it had to be continuously supported; it was for this reason that a Ladies' Auxiliary was being formed.

Glasgow Victoria Infirmary.

The annual meeting of contributors to Glasgow Victoria Infirmary was held on February 19th, with Lord Provost Kelly in the chair. The report showed that the expenditure on the Infirmary, the auxiliary hospital at Philipshill, the Bellahouston Dispensary, and the convalescent home at Largs had amounted last year to £61,559, while the subscribed income had been £27,909. The deficit had had to be met from legacies and special donations. Recent additions to the Infirmary had greatly increased the cost of maintenance, and an appeal was made for larger annual subscriptions and donations. During the year 6,355 patients had been treated in the hospital, of whom 4,569 belonged to Glasgow and 1,783 to other parts of Scotland. Employees' contributions had amounted to £11,533, an increase of £77 on those of the previous year, while contributions received from patients had totalled £1,257, an increase of £37 over the amount from this source in the previous year. Mr. William Gray, chairman of the governors, said that the new auxiliary hospital at Philipshill had been in operation for six months. A block for paying patients had been erected at Langside, and the governors expected this would be ready for occupation in the autumn of the present year. It would be a very important extension of the hospital service, and would be rather an experiment for this country, because other districts had very little experience of paying hospitals. There had been need for paying blocks in London and a few other big towns, but as methods of administration varied considerably the governors had largely to form their own plans. They had decided to make one inclusive fee for all patients, irrespective of the nature of the case, and this fee would include every charge, so that the patient would know exactly to what extent he was financially committed. Should there be a growing demand for this method of treatment, the large general voluntary hospitals would have to consider whether their present activities should be extended, or whether special hospitals should be built to treat only patients of moderate means, who would pay the cost incurred. The most efficient service could undoubtedly be given by a large institution having command of capital to install the most modern equipment. Mr. John Dallas, in referring to the maintenance of voluntary hospitals, said that, if they were insufficiently supported, a rate of about 4d. in the £ would have to be levied.

Glasgow Royal Asylum.

At the annual meeting of contributors to Glasgow Royal Asylum, held on February 20th, Dr. D. K. Henderson, physician-superintendent of the institution, said that during the last few years he had attempted, in his annual reports, to educate the public to recognize the importance of maintaining the mental health of the individual for the welfare of the community. The mental hospital was the last resource when other means of treatment had been exhausted, and the public should think in terms of prevention rather than of cure. This fact had been widely recognized in America by the establishment of psychiatric institutions as centres from which a campaign regarding mental hygiene could be launched. In Scotland, on the other hand, neither public nor private philanthropic enterprises had taken much interest in the problem of mental health, and he pleaded for the establishment of a psychiatric institute in every university town where there was a teaching hospital. Such an establishment, in his opinion, would set a standard for psychiatric work throughout the country, and would act as a training centre for all who were concerned and interested in the problem of mental health. The allied problem of mental deficiency was very large. According to the recent report of the Mental Deficiency Committee, an average of 8.55 per 1,000 of the population in England was definitely mentally defective. This figure was double that reported by the Royal Commission of 1908, and when applied to the whole of England and Wales there appeared to be about 340,000 mentally defective persons. A feasible plan seemed to be to develop the system of colony care; the directors of the asylum had considered many places in this connexion. The days of regarding the mentally ill as "lunatics" had now passed. It was proposed that the institution should be known in future as the Glasgow Royal Mental Hospital.

Central Midwives Board.

The examinations of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, have just concluded with the following results. Out of 97 candidates who appeared for the examination 93 passed. Of the successful candidates 25 were trained at the Royal Maternity Hospital, Glasgow; 25 at the Royal Maternity Hospital, Edinburgh; 2 at the Maternity Hospital, Aberdeen; 4 at the Royal Infirmary, Dundee; 11 at the Elsie Inglis Memorial Hospital, Edinburgh; 4 at Stobhill General Hospital; 3 at Barshaw Hospital, Paisley; 5 at the County Maternity Hospital, Bellshill; and the remainder at various recognized institutions.

A Health Exhibition.

An exhibition of health and hygiene, organized by the medical officer of health, Dr. William Robertson, will be held from March 12th to 29th, in the Waverley Market, Edinburgh. The Public Health Department will exhibit tableaux of its activities, especially with regard to dietetics, and various demonstrations of cookery will be given for the wives of working men. The child welfare

department will show the training of the pre-school child, the use of artificial sunlight, lamps, etc. There will also be exhibits of new houses and gardening, and practically all the departments of the city corporation will be represented.

Sydney Professorship.

Dr. Charles George Lambie, *M.C.*, F.R.C.P.Ed., has been appointed to the Bosch chair of medicine in the University of Sydney. He is 38 years of age, and graduated M.B. at Edinburgh in 1914, and M.D. in 1927, when his thesis was awarded a gold medal. During the war he served in the East as captain in the R.A.M.C. He has been an assistant physician to the Edinburgh Royal Infirmary and lecturer in medicine in the School of Medicine of the Royal Colleges, Edinburgh.

England and Wales.

Cumberland Infirmary.

At the recent meeting of governors of the Cumberland Infirmary the resignation of Dr. H. A. Lediard as surgeon to the Infirmary was accepted with regret. The chairman, Mr. Carr, announced that the governors had elected Dr. Lediard honorary consulting surgeon in recognition of fifty years' distinguished service. Tributes were also paid by the mayor of Carlisle and by Dr. Maclaren, who spoke on behalf of the staff. Mr. Hartley referred to the contributions Dr. Lediard had made to the application and development of modern surgery. When Dr. Lediard began his studies in Edinburgh, he said, epidemics of typhus and typhoid were prevalent, and wards in the old Edinburgh Infirmary had to be set apart for such cases. There was no efficient nursing. The surgical wards were full of sepsis. Dr. Lediard came to Carlisle, having been trained at first hand by the pioneers of antiseptic methods. At the annual meeting of subscribers, on the same date, Dr. Lediard was elected an honorary vice-president.

In moving the adoption of the eighty-ninth annual report and financial statement the chairman alluded to the probable effect of the Local Government Act of 1929. Cumberland Infirmary, he said, desired to retain its independence as a voluntary institution, and its position as such was not likely to be endangered by the new conditions. A rate of a shilling in the pound on poor rate assessment would have to be levied if the expenditure of the Infirmary became a charge upon the rates of the city. He expressed satisfaction with the progress of the building extensions. The new pathological laboratory had been completed, a radium fund instituted, and two new wards would soon be ready to accommodate about forty additional beds. Work in all departments had increased during the year, particularly in out-patients' attendances, which exceeded the figure of 1928 by almost 9,000. Treatment of motor accident patients, however, had incurred a cost of £423, of which only £74 had been recovered. He felt that some system of compulsory insurance should be devised to ensure the recovery at least of costs of maintenance, drugs, dressings, etc., and surgeons and physicians might receive a special fee for their services in this connexion.

Proposed Health Centre at Becontree.

The London County Council, which owns the large housing estate at Becontree, near Ilford, is proposing to erect there a building to accommodate a health centre, together with an out-patient department of the new King George Hospital at Ilford, and provision for certain local health services. When the appeal for the King George Hospital was launched the council agreed to make a contribution of £10,000 towards the capital cost, conditional upon the rights of its tenants at Becontree as regards treatment at the hospital being safeguarded. The hospital will eventually consist of 300 beds; the amount raised up to the present is nearly sufficient for the completion of the first portion, consisting of 150 beds and the administrative offices. It is found, however, that there is need for the provision on the estate itself of a health centre. King George Hospital, though planned at no great distance, will not be actually on the estate. The hospital authorities will be responsible for the running of the building, and will obtain some part of the cost of maintenance from the local authorities (Essex County Council and Dagenham Urban District Council), whose health services will be carried on there. The council proposes to let on long lease to the hospital authorities a suitable site at a nominal rent, and to make a total grant of £6,500 towards the capital cost, which is expected to be, for building, about £7,770, and for equipment, a further £1,080.

The Home Office Industrial Museum.

The Home Office Industrial Museum, which was inaugurated two years ago by the King and Queen, when it was the subject of an article in these columns (December 10th, 1927, p. 1110), has received some interesting additions. A small building has been erected in the yard of the museum to demonstrate the effects of unfavourable atmospheric conditions in workrooms, and the way in which, by inducing air movements and employing different methods of heating, such conditions can be remedied or their effects mitigated. Another section of the museum draws attention to the disastrous effects of certain kinds of stone dusts upon the lungs of workers. Two huts have been installed in which a pneumatically operated stone dressing plant, equipped with a new method of trapping the dust near the cutting tool point, is demonstrated. A method recently installed in some city buildings for deadening the effect of noise by means of a ceiling lined with special padding is shown, and another exhibit illustrates the explosive properties of dusts of common substances, such as flour and starch. A number of the exhibits have a "safety" value. These include various protective devices for use with machinery, such as a new mincing machine so designed that it is impossible for the fingers to be caught in the worm, an interlocking device for lift gates, and an apparatus for holding aerated water siphons when the heads are being polished, so as to prevent the worker from being injured in the event of the bottle bursting. The existence of this museum is perhaps not generally known; it is situated in Horseferry Road, Westminster, is open both morning and afternoon of every weekday, and is well worth a visit by those who are interested in health and safety (and incidentally in labour-saving) in industry.

British Spas Federation.

At the annual meeting of the British Spas Federation, held recently in London, at which representatives of Bath, Buxton, Cheltenham, Droitwich, Harrogate, Leamington Spa, Llandrindod Wells, Trefriw Wells, and Woodhall Spa were present, it was agreed that financial support on a basis of £1 per 1,000 head of population be again given to the Travel Organization of Great Britain and Ireland, a body which undertakes extensive publicity work abroad in order to make the attractions of this country better known to other nations. The hope was expressed that the lead of the Federation would be followed by other resorts. It was reported that an international and national register of spas of the world was in course of preparation under the aegis of the International Society of Medical Hydrology, the intention being to give the medical profession the scientific and relevant data of each spa in such a concise form as would afford an easy method of comparing the values of their waters. Analyses of the mineral waters are to be expressed in standardized terms, and the Federation, in support of this scheme, is instructing its members to arrange that all analyses shall be prepared in the prescribed manner. British spas generally reported an increasing number of visitors for treatment during 1929, and in several instances this increase was about 20 per cent. above the average numbers of the three previous years. English people were beginning to recognize that the spas of this country had generally reduced their charges for treatment, to bring them within the means of the majority of people. British spas had modernized their buildings, and with the use of up-to-date equipment and the giving of treatment by qualified attendants only, they had created a standard of efficiency which was bound to attract visitors. It was announced that a new medical handbook, available only for members of the medical profession, was about to be published, and an invitation to hold the Federation's autumn meeting at Harrogate was accepted.

Correspondence.

MEMBERS OF THE ROYAL COLLEGE OF SURGEONS.

SIR,—Since the encouragement which those of us who are responsible for a direct move to obtain representation of Members upon the Council of the Royal College of Surgeons of England have recently met with, we have received promises that should enable us soon to invite from the Members themselves a material expression of their adherence.

On February 14th Professor Hey Groves, in the Hunterian Oration (published in your last issue) referred in generous and valuable terms to our movement. He pointed out that for over thirty years the governing body of the College had been requested to consider the situation, and alluded to the phase of amity and good temper which at last marks the discussion of the question at the annual meeting of Fellows and Members. But he went on to point out that, unless a substantial number of the 18,000 Members record their view that the reform is desired, the Council of the College may well decline to believe that the modern and democratic aspect need be adopted. "The chief thing," said Professor Hey Groves, "which is needed to bring this about quickly is convincing evidence that the change is desired by the great body of the Members."

A circularizing of the Members will shortly take place, and it is earnestly hoped that replies will be received from a substantial number—why should it not be signed by them all? The small sum of £250 is required to defray the cost of the circular. A proportion of this has already been received, but our treasurer, Dr. K. Barrett, 102, Church Street, London, S.W.8, will gladly receive and acknowledge further contributions, which are needed.—I am, etc.,

London, W.1, Feb. 23rd. ERNEST E. WARE.

"PHYSIOLOGICAL DILATATION OF THE HEART."

SIR,—I much regret that my allusion to Dr. K. D. Wilkinson as an uncompromising opponent of the views which I endeavoured to expound should appear to him as incorrect or unfair; but I am glad that it should have provided him with the opportunity for giving wide publicity to the calculations which he thinks must demolish my contentions. The more light we have on the matter the better. But our interesting correspondence left us each unconvinced by the arguments that appealed to the other: and though in his letter in the *Journal* of February 22nd (p. 360) he states that he is in agreement with the majority of my views, he proceeds to demolish the conclusions to which I was led, and ends by "joining issue" with me on the vast and vexed question of "dilatation and the strained heart," which is nowhere alluded to in my paper, on which I have expressed no opinion, and which is quite foreign to the subject of *physiological* dilatation. I confess that I still regard him as an uncompromising though a quite friendly opponent.

To quote my own words, "If I am wrong in these surmises, then there must be some other explanation." But Dr. Wilkinson's explanation fails to satisfy me. He believes in "distension," by which I presume he means something more than "relaxation," but not in "dilatation." The latter is the word which was always used by Starling, and which I adopted; but, in this connexion, the words appear to me to be synonymous. In the case described by me the area of visible and palpable pulsation was stated to be "rather diffuse," yet it was strictly limited to the fourth and fifth interspaces from somewhere near the sternum to "outside the anterior axillary line at the nipple level." Dr. Wilkinson believes that this was caused, not by dilatation, but by a "forcible" impulse which "was conveyed to the whole chest." I do not share this view. How far the area of visible and palpable pulsation may be increased by "conduction" I cannot say, but that it is inherently dependent, in these circumstances, on physiological dilatation I entertain no doubt.

Several other statements in Dr. Wilkinson's letter invite discussion; but space forbids. May I refer to one? The definition of the apex beat—"the furthest left and the furthest down of defined pulsation"—cannot apply where these two points do not coincide, and I do not think that *the point of pulsation felt furthest out is*, in these cases, the true apex, a view which the Harvey film incident referred to in my paper seemed to confirm. At each beat the anatomical apex, which was very obvious, seemed to give a twist, but not to shift much in position, while the enlargement of the heart proceeded progressively above it. I am speaking from memory, but I feel sure this was the case.

I am glad to be able to record that I have received striking encouragement from many distinguished colleagues upholding the views which I endeavoured to expound, and three cases have been reported to me which had puzzled the observers, but which these views would seem to explain. In one of these cases the observer was able to reproduce the phenomenon experimentally. I hope that some occasion may arise when the subject of physiological dilatation and what Sir Thomas Barlow alluded to, in conversation, as "its fringes" may receive adequate discussion. But the time may not yet be ripe.—I am, etc.,

Tunbridge Wells, Feb. 22nd. CLAUDE WILSON.

DISINFECTANTS IN MIDWIFERY.

SIR,—The London County Council has done an important public service in issuing a statement condemning the use of lysol in midwifery. It is a fact known to too few people that the germicidal action of lysol on streptococci is totally inadequate in the dilutions which its caustic properties demand for clinical use.

The statement to which I refer (quoted in the *British Medical Journal* of February 22nd, p. 359) may be misapprehended in that it implies a virtue in certain brands of lysol which is not possessed by others. I had occasion to test the germicidal properties of several brands of lysol about two years ago, and the results were surprisingly uniform. Two English, two American, and one German brand were all incapable of killing *Streptococcus pyogenes* in dilutions commonly employed in midwifery, even under favourable conditions. That there may be brands more unsatisfactory than these is possible, but I say without hesitation that there is no lysol the use of which in midwifery can be anything but a delusion and a danger. Lysol has an adequate germicidal action only on Gram-negative bacteria, and its use should be restricted to such purposes as the disinfection of excreta and utensils.

It is at least arguable that much puerperal sepsis as it occurs to-day could be prevented by the use of an efficient antiseptic. I suggest that careful laboratory tests of the efficiency against *S. pyogenes* of all antiseptics suitable in other respects for obstetric use are an urgent necessity. There are at least two coal-tar antiseptics the action of which on streptococci is far superior to that of lysol; it may be that mercury salts, as suggested by Dr. Gutch in your issue of February 22nd, are better still.

The choice of an antiseptic, whether in surgery or in obstetrics, should surely not be a matter of personal taste, like choosing a wallpaper; it is a matter of facts and figures. The best agent is that which will destroy the particular organism against which it is to be used in the highest dilution relative to the minimum tolerated by the tissues, in the shortest time, under conditions simulating as far as possible those of its practical employment. All other considerations are secondary to this if its use is designed to avert a serious danger.

This is a neglected subject: information on it is scattered and scanty, and some is probably not to be found at all. If full data were available as to the action on different organisms of all the antiseptics in common use, lysol might not be the only idol to come crashing to the ground.—I am, etc.,

Harpenden, Herts, Feb. 24th. LAWRENCE P. GARROD.

RECTAL EXAMINATION DURING LABOUR.

SIR,—Everything written by Dame Louise McIlroy on her own subject deserves attention, but with part of her address reported in the *Journal* of February 15th (p. 269) I *hope many will disagree. She says, quite rightly,* that vaginal examination in normal cases ought to be unnecessary, but in the next paragraph goes on to say that rectal examination is also to be discouraged. Surely, except in hospital perhaps, or where the doctor is prepared to stay in the house the whole time, pelvic examination is a necessity. How else can he judge, with any approach to accuracy, when to go away (and for how long) and when to stay? When to give sedatives and when pituitrin? And so on.

A good rule is—"Never give reasons." But since Dame Louise has given hers I hope she will not mind if I attempt to deal with them in the light of several years' experience.

1. "I think it is an objectionable method of examination" and "the patients dislike it." Ought either of these to carry any weight whatever as compared with the importance of avoiding infection? Moreover, I find that the patients do not mind at all; besides, it is easy to explain.

2. "For a period of eighteen months we tried rectal examinations. The sepsis rate was increased rather than diminished." I should have suggested that her hospital had already attained the irreducible minimum if Dame Louise herself had not questioned whether every student and midwife could be trusted to see that the gloves are *sterilized after rectal examination. (I had always thought* that the ladies were more conscientious than their brothers, rather than less!) If students are allowed to make neither vaginal nor rectal examinations, how can they become efficient? Dr. Claye reported in the *Journal* of July 20th, 1929 (p. 90), that in his hospital pyrexia occurred approximately half as often in those examined per rectum as in those examined per vaginam. My own experience of the last nine years leaves me in no doubt that his figures do not in the least exaggerate.

3. "It causes pain if the head is low or if haemorrhoids or oedema are present. If the rectum has cracks or sores the risk is increased. The finger in the rectum tends to push up the posterior lower vaginal wall and infect the cervix." Surely these objections are *wholly hypothetical* and of no real importance? If the vaginal wall may infect the cervix, how much more the vaginal finger?

4. "It is difficult to diagnose the degree of dilatation of the cervix." With very little practice it is surprisingly easy in the majority of cases. My nurses have learnt it without much difficulty.

5. "It is difficult to diagnose . . . the presenting part if a caput is present, and also to feel a prolapsed cord if pulseless." Normally ante-natal work or abdominal examination has revealed the presentation—and, any way, even per vaginam the sutures are seldom helpful to most of us in really doubtful cases. If the cord is already pulseless, does it matter much whether it is discovered early or late? Besides, does the cord prolapse often enough in vertex presentations to make this a serious consideration?

My practice is to examine per rectum with a finger-stall. Should I be in serious doubt, and if it is important to know at once, I wash up and put on my gloves to examine per vaginam. In my first year I delivered seven out of every ten normal cases—including a large proportion of primiparae—without vaginal examination. Last year, an exceptionally good one, the proportion was nine out of ten of *all* my cases. In my view the rectal method is the one useful and universally applicable advance in the practice of aseptic midwifery which has been made in recent years; and I would beg Professor McIlroy, casting aside her personal predilections, to go to her own labour wards, and, in a truly scientific spirit, personally to try out this method on a considerable sequence of cases.

If the method is the good and sound one which we believe it to be, as soon as its practice becomes general the morbidity rate of normal cases will be reduced to that of "B.B.A.'s" and the investigation of the causes of puerperal infection will be correspondingly simplified.—I am, etc.,

London, S.E., Feb. 17th. W. M. PENNY.

QUININE IN NORMAL LABOUR.

SIR,—Induction of labour is a difficult problem for the general practitioner. He has the choice between medical and surgical induction. Naturally he prefers the medical induction to the surgical, as there is no necessity for an anaesthetic nor is there risk of septic infection.

The *method that I* used to employ was as follows. One ounce of castor oil was given, followed by a hot bath for ten to fifteen minutes; a tight binder was then applied, and a simple enema given three hours after the oil. One hour later 10 grains of quinine was given with a hot drink, and repeated every two hours for three doses. This was *frequently successful,* producing a tempestuous and quick labour, but on several occasions the baby was born dead, the cord was pulseless, and the baby very cyanosed. Consequently I gave up this method of induction and employed the method of inserting two or three No. 12 bougies between the membranes and the uterus.

The babies were well nourished and healthy looking. I performed a necropsy on one of them, but found no pathological explanation. On two occasions the Wassermann test gave negative results. In each case the mothers subsequently gave birth to healthy live babies without quinine induction.

I should like to know whether others have had similar experiences with this quinine induction, or whether these few cases were accidental.—I am, etc.,

Northwood, Feb. 21st. D. D. RITCHIE.

ANAESTHETICS IN MIDWIFERY.

SIR,—Can anything be done to stem the tide of misdirected enthusiasm in matters medical, of which the proposal recently ventilated in the press to found a fund for the provision of anaesthetics for mothers is the latest example? Anyone reading this appeal would be led to think that anaesthetics in childbirth are denied to the poorest, and can only be obtained by those who can afford to pay for them, whereas, under the existing machinery of the Midwives Act, the very poorest mother can have the services, when necessary, of an anaesthetist, in addition to the doctor in attendance, at her own home without any expense, and should she be in any hospital or institution there are always medical men in charge or certainly available. Therefore the implication that a fund is needed for "the provision of anaesthetics for mothers in institutions and hospitals" is false. To suggest that, on the ground of expense, the blessings of an anaesthetic are unavailable for the poor mother is not in accordance with fact or practice. If, in the opinion of the medical man attending any woman in labour, the necessity for an anaesthetic arises, then it is available and given to rich and poor alike, the question of expense in the latter case not having to be taken into consideration, owing to the provisions under the Midwives Act. Anaesthesia properly used at the proper time is indeed a blessing, but unless there are indications for its use in any individual case it may do positive harm, and the discretion for its use must be left to the medical attendant for both rich and poor. Every mother has the right to the services of qualified help, paid for by the State, when her circumstances are needy, and such a fund as that outlined is therefore unnecessary.—I am, etc.,

Lichfield, Feb. 16th. F. M. ROWLAND, M.D.

TOXIC EFFECTS OF METHYL CHLORIDE GAS.

SIR,—Dr. Buckley Sharp's account, in your issue of February 22nd (p. 336), of two attacks of poisoning due to the escape of this gas from leaks in refrigerators interested me, as on the previous night, at the Institute of Chemistry, I referred to twenty-nine cases, with ten deaths, from the same cause in Chicago in 1928. I had it down that similar cases might be reported at any time in this country.

A detailed account of the Chicago cases is given in the *Journal of the American Medical Association* of August 3rd, 1929.[1] The outstanding symptoms found were drowsiness, mental confusion, coma, vomiting, and, in severe cases, convulsions. Temperature, pulse, and respiratory rate

[1] "Methyl Chloride Poisoning from Domestic Refrigerators." By Drs. A. H. Kegel, W. D. McNally, and A. S. Pope.

were all increased, and anuria usually occurred. The sequels noted were suggestive of injury to nerve cells, followed by progressive degeneration. In nearly all of the cases a tentative diagnosis of food poisoning had been given.

Some risk of fire and explosion accompanies the use of methyl chloride, and, as a suggestion was made to use a non-inflammable mixture by employing the known extinctive properties of the corresponding methyl and ethyl bromides, some very useful animal experiments were carried out by the highly skilled staff in the Bureau of Mines of the National Research Council.[1] Briefly, for short exposures of guinea-pigs to high concentrations, ethyl chloride was found to be the least, and methyl bromide the most, toxic of the four compounds. Methyl chloride and ethyl bromide occupy intermediate positions.

The maximum amount for prolonged exposure of animals to methyl chloride they put down as from 5 to 10 parts per 10,000 of air. A distinct delayed effect of exposure was observed with methyl bromide and methyl chloride, this usually occurring after exposure to moderately low concentrations.—I am, etc.,

London, S.W.1, Feb. 25th. T. M. LEGGE.

SIR,—I was interested to read Dr. B. Buckley Sharp's notes of two cases of poisoning by methyl chloride gas in people working with refrigeration plants. In June, 1927, I was called to attend a case which seems to support his conclusions.

A man, aged 35, had had to work in the cellar of an hotel in Carlisle fixing a refrigerating plant. Normally he would not have had much to do with the actual installation, but, some mechanical fault having occurred, it was necessary for him to attend to it himself. The fault caused some escape of gas, and he was working in the confined atmosphere for several hours. On ceasing work he felt giddy and slightly sick, but drove his car back to this city—a distance of sixty miles—having to stop twice owing to attacks of vomiting. I saw him shortly after his arrival, when he complained of vomiting, giddiness, and diarrhœa, although the diarrhœa was not very severe. His pulse was 110, respirations 27 per minute, and he felt faint. He was slightly cyanosed, and the apex beat was just outside the mid-clavicular line. On auscultation there was a soft blowing systolic murmur at the apex, but in other areas the heart sounds were not easily heard. The lungs showed no abnormal signs, nor did any of the abdominal viscera.

The diarrhœa had practically ceased next day, and the cyanosis had gone, but he was still giddy, and vomited for another two days. After the fifth day he seemed to have lost all his symptoms, the apex beat was inside the mid-clavicular line, and the heart sounds were normal, but he stated that he felt weak and shaken, as if he had had an acute illness.

I saw him for the last time on the tenth day after the exposure, when he stated that he felt much better. He returned to work the next day.

Four and a half months later I saw him again, when he was suffering from an acute pleurisy. He then stated that he had kept quite well in the meantime, and had not had any occasion to be in close contact with methyl chloride gas.

At the time I could not find any reference to cases of poisoning by methyl chloride gas, and, on reading of the two cases reported by Dr. Buckley Sharp, I thought that notes of a third case might prove of interest. One point in this case—the cardiac dilatation, with slight cyanosis, which was not present in Dr. Sharp's cases—I took to be due to the strain of travelling sixty miles in a car, the exertion of driving having caused the overstretching of a poisoned myocardium.—I am, etc.,

H. BRENTON PORTEOUS, M.B., Ch.B.

Newcastle-on-Tyne, Feb. 22nd.

VISUALIZATION OF THE INTRAHEPATIC DUCTS.

SIR,—In the *British Medical Journal* of February 15th (p. 279) Dr. C. J. Fuller reports a case of visualization of the intrahepatic ducts after an opaque meal had been given to a patient who was thought to have a cholecystocolic fistula. He states that he has been unable to find records of any similar case.

In the *Guy's Hospital Reports* for January, 1929, I reported with Dr. P. J. Briggs two cases of "visualization of the bile ducts after an opaque meal." In the first case the barium only entered the dilated common duct for a short distance, and was there obstructed by the presence of a large single calculus. In the second case the intrahepatic ducts were clearly seen.

The condition responsible for the picture in the second case differed from that reported by Dr. Fuller. Four years previously the patient had a growth of the splenic flexure excised, together with a portion of the greater curvature of the stomach, to which it was adherent. Four years later epigastric pain associated with copious vomiting commenced. The *x* rays revealed obstruction just distal to the duodeno-jejunal flexure with great dilatation of the duodenum. A small sac situated above and to the outer side of the duodenal bulb was seen to fill. A radiogram taken when the duodenal distension and oscillation were at their height gave a beautiful picture of the branching intrahepatic ducts filled with barium, in addition to the small sac which had been visible on the screen.

At the subsequent operation a growth was found involving the greater curvature of the stomach, the jejunum, the spleen, and the pancreas. The jejunum was infiltrated in its whole circumference; this portion was freed from the main mass and resected, and an end-to-end anastomosis performed. The gall-bladder was extremely small and embedded in fat. The patient survived for a year, and was relieved of the symptoms caused by the small intestine obstruction.

In this case the opaque meal ascended the common bile duct and entered both the gall-bladder and intrahepatic ducts as a result of the enormously increased intraduodenal pressure produced by the obstruction.—I am, etc.,

New Lodge Clinic, Feb. 17th. JOHN F. VENABLES.

THE ETIOLOGY OF DENTAL CARIES.

SIR,—In the article on Mrs. Mellanby's work which appeared in your issue of February 15th (p. 292) you state as her main conclusion that

"the minute structure of the developing tooth and the reaction of the developed tooth to caries are influenced by the chemical nature of dietetic ingredients, which, after being digested and absorbed, are carried in the blood stream to the tissues of the body, and thus to the teeth."

A little analysis of a few well-known facts shows that this theory fails to throw any light on the incidence of caries as revealed by statistical examination of the teeth in civilized communities.

Let me refer to a few of the facts which the reader may easily be able to verify. In looking into the mouth of a civilized being still possessed of a fair number of teeth, it will very generally be found that the lower incisor teeth are all free from caries, while the molars are carious, filled, or lost as the result of the disease. It is well within the mark to say that the molar teeth succumb to caries twenty-five times more frequently than do the lower incisors. How can we account for this? Are we to believe that the "dietetic ingredients" after being digested and absorbed affect the molars, though these same ingredients in the same individual do not similarly affect the incisors? It may be said that the times of calcification are different, but the dietetic ingredients in civilized diets are fairly constant, and with regard to the first molars the time of calcification of the crown is approximately the same as that of the lower incisors. Nevertheless, these molars become carious nearly forty times more frequently than the lower incisors. It may further be pointed out that the lower incisors are formed approximately at the time when rickets is most likely to be present (6th month to 2½ years), whereas the crown of the second molar is calcified after this period (4th to 8th year), and the third molar is calcified after the period of liability to rickets is long past (8th to 12th year). It would thus appear that vitamin D or any other dietetic ingredient, after absorption, does not account for the incidence of caries in the mouth. Of course it is easy to explain the relative frequency of caries in different teeth on what you refer to as the "hitherto generally prevailing view that the production of dental caries depends almost exclusively on conditions external to the teeth," for, otherwise, no doubt, such view would never have prevailed.

[1] "Physiological Response Attending Exposure to Vapours of Methyl Bromide, Methyl Chloride, Ethyl Bromide, and Ethyl Chloride." By R. R. Sayers, W. P. Yant, B. G. N. Thomas, and L. B. Berger. *Public Health Bulletin*, No. 185. 1929.

Let me refer now to the quotation given from the introduction to Mrs. Mellanby's experimental study.

"It is well known that some people with neglected mouths have teeth free from caries, whereas others who take great care in matters of oral hygiene have extensive caries. In fact, the most rigid adherence to the commonly accepted rules of dental hygiene constitutes no safeguard against a dental disease."

I, at least, have long since noted that the "commonly accepted rules of dental hygiene" were of but little value in preventing caries; in fact, I often noted that the greater the care, the worse the teeth. But, unfortunately, it invariably turned out to be misdirected care. To put reliance on a toothbrush and antiseptics after eating viscid, fermentable carbohydrates which clog up the crevices of the teeth and between them is only courting trouble. Neglected mouths and dental mal-hygiene, moreover, do not necessarily predispose to caries. The unhygienic conditions resulting from neglect may indeed be rather antagonistic to the onset of caries, for there are two types of oral mal-hygiene, one of which leads to the formation of acid from carbohydrates, and the other, from proteid matter, to an alkaline reaction often associated with the deposit of tartar, pyorrhoea, and brownish stains on the enamel. This latter type of oral mal-hygiene is aggressively conspicuous, but it is not directly at least, and for obvious reasons, conducive to caries.

If research workers and medical men generally would turn their attention to considerations of the physiology of oral hygiene—to conditions external to the teeth—and accept what is, or ought now to be, definitely known—namely, that the degree of calcification or quality of the tooth has nothing whatever to do with the production of the acid which initiates caries in the enamel—then the evil results of widespread misdirected care would be averted.

May I, in conclusion, say that I am not unmindful of preventing any conditions which might result in the formation of hypoplastic teeth, and thereby possibly predispose them to caries as the result of carbohydrate stasis? Further reference to this is, however, unnecessary here, as hypoplasia practically always seems to result from febrile diseases, syphilis, or derangements in digestion, and rarely, if ever, from lack of a sufficiency of vitamin D, when hygienic conditions are attended to.—I am, etc.,

London, W.1, Feb. 16th. J. SIM WALLACE.

ANAESTHESIA FOR SHORT OPERATIONS ON CHILDREN.

SIR,—In his letter in the *Journal* of February 1st (p. 217), Dr. H. Sington asserted that "guillotines at the Hospital for Sick Children, Great Ormond Street, were relegated to the museum before this method of administering ethyl chloride came into general use." This assertion is doubtless true so far as it concerns that hospital, and was probably due to the fact that one or more surgeons there elected to use another method, but "it would be unwise," to quote the words of Dr. Sington's letter, "to allow to go unchallenged" such a statement, in case it led to some misconception in the minds of others as to the merits of the guillotine operation and those of tonsillar dissection. Had Dr. Sington added that the men who were unable to use a guillotine and who persisted in using it should also be relegated to the museum, one would have agreed with his otherwise ambiguous statement. Very many experienced laryngologists use the guillotine, or some modification of the Beck tonsillectome (snare), which is employed in the same way as the guillotine, and are able to show as good results, such as a smooth clean wound bed without injury to the underlying structures, the after-appearance of the fauces, and, of course, a complete removal of the tonsil with its capsule (tonsillar layer of the pharyngeal fascia, and really an artefact), as those obtained by any other known methods.

The method of removal or enucleation of tonsils by the guillotine was conceived and introduced by Mr. Samuel S. Whillis in the throat and ear department of the Royal Victoria Infirmary, Newcastle-upon-Tyne, in 1910, and its technique was published in the *Journal* (1911, vol. ii, p. 1402). It still stands as the accepted best guillotine operation. Small and large, buried or submerged, and prominent tonsils lend themselves alike to easy and complete extirpation. A certain (small in the year's work) proportion of tonsils, bound down and embedded in dense capsular adhesions, and scarring of the bed due to recurrent attacks of peritonsillitis, etc., must of necessity be dissected out. One has seen the results of "bungling" with the guillotine, such as incomplete removal, or laceration of the anterior pillar and soft palate, and there are yet many operators who attempt to employ the Whillis method with a sharpened blade, which, of course, is asking for trouble. This is simply due to ignorance and failure to take an opportunity of seeing and thoroughly learning the proper use of the instrument.

The same strictures apply exactly to dissection, which in the hands of an incompetent operator will result in bruising and laceration of the layer of tissue containing the vessels and muscle bed, causing much haemorrhage at the time, delayed healing of the wound, and prolonged discomfort to the patient, together with the prospect of a mass of granulations and scar tissue forming in the fossa, followed by actual keloid growth.

Let us therefore boil down the argument to this, that every young surgeon desirous of including the removal of tonsils in his practice should first attend a post-graduate course at a university clinic, where he can see the one or the other method properly carried out and taught. He can afterwards decide which method will suit his own particular *flair*—if he indeed possesses this inestimable and somewhat instinctive quality in a surgeon. One repeatedly hears the remark, "Oh, anyone can take tonsils out," but it is the patient, unfortunately, who awakens to appreciate this delusion.—I am, etc.,

February 21st. W. FRANK WILSON,
Honorary Assistant, Throat and Ear Department, Royal Victoria Infirmary, Newcastle-upon-Tyne.

AN ALTERNATIVE TO THORACOPLASTY.

SIR,—The following is an account of an idea which I have had in mind for some time for an alternative operation to thoracoplasty. As we have no operating theatre here I am unable to perform the operation myself, and I am hoping that you will publish this so that others may try it. It was originally devised for cases of single pathological pneumothorax without effusion, and in which the other lung is free from disease. After the initial shock of the pneumothorax has passed, and preferably when the collapse has become complete, or nearly so, would appear to be the best time for operation.

For a left pneumothorax the precedure is as follows: The surgeon stands on the right side of the patient and makes a left rectus incision of considerable length, starting just below the diaphragm and continuing downwards as far as may be necessary. The rectus muscle is deflected and not cut. The posterior wall of the sheath of the rectus muscle is divided, but the parietal peritoneum must be left intact. The surgeon then introduces the right hand and separates the liver from the undersurface of the diaphragm and makes a horizontal incision in the diaphragm, keeping to the outer half and carefully avoiding injury to the pleura. A retractor is inserted into this incision and is held vertically. The right hand is now passed through the diaphragm and the pleura (diaphragmatic and parietal) is carefully stripped from diaphragm and chest wall respectively. The parietal pleura is now placed in apposition to the visceral pleura. The incision in the diaphragm is next repaired and the abdominal wound is dealt with in the usual way. It is necessary to leave the left side of the thorax open to atmospheric pressure in order to maintain good collapse. I think removal of a piece of intercostal muscle without interference with ribs should suffice if the wound is carefully kept open. Later on, when disease of the lung is considered to be arrested, this wound could be allowed to heal. In right-sided pneumothorax the surgeon would, of course, stand on the left side of the patient and would perform the pleura stripping with the left hand.

Ether is contraindicated, as most of the cases are tuberculous in origin, and I think oxygen should be used as the patient has only one lung. If sufficiently deep and prolonged anaesthesia is possible with gas and oxygen this would seem to be ideal; if not, chloroform and oxygen should be satisfactory.

It is practically certain that the two layers of pleura will become adherent and so seal the pathological perforation and prevent further mischief. If pleural effusion is present it should be removed by an assistant in the usual way before the pleura is stripped. If the lung is really collapsed before the operation is started shock should be a very small factor, and in any case it should be much less than that caused by thoracoplasty.—I am, etc.,

B. LAYTON LLOYD,
Medical Superintendent, The Mount Sanatorium, Bishopstoke, Hants.

February 10th.

"TENNIS ELBOW."

SIR,—The discussion of this subject has led us into many interesting pathological by-ways, and has indeed justified your editorial remarks as to the obscurity of tennis elbow. It might have been hoped that the controversy would centre around the cause and cure of the condition rather than around vague pathological surmises which, even when sponsored by eminent surgeons, are likely to remain merely surmises in the absence of visual proof.

It would seem that there are many varieties of tennis elbow—or is it, as has been suggested, that there are many observers? I fancy the latter must be the case, for all the examples which I have seen have been remarkably similar in symptoms. They have all had pain in the region of the elbow-joint, and this pain is of two kinds; there is a dull ache which is more or less always present, and there is the sharp spasm of agony which only comes on when some movement is performed; the two forms of pain are also met with in other muscular affections, such as lumbago, for instance. The dull ache is localized around the insertion of the extensors and supinators into the external condyle of the humerus and the bony ridge running up from it to merge into the shaft of the bone. The spasmodic pain is not so localized, and may be felt anywhere around the joint or in the forearm.

Among the several comments of your correspondents on my letter on this subject published on December 28th, 1929, it is disappointing that none referred to my theory as to the cause of tennis elbow—namely, that it is due to the prolonged act of grasping an instrument of any sort—for many of my cases were due to the use of such diverse objects as a wood-saw, a weeding tool, a hammer, and an oar.

My only comment on the pathology of tennis elbow is this—that though we all have lumbar muscles we do not all get lumbago.—I am, etc.,

W. H. EDGAR,
Surgeon Commander R.N.

H.M.S. *St. Vincent*, Feb. 16th.

*** This correspondence is now closed.

DISPOSAL OF THE DEAD.

SIR,—We doctors know that there is considerable difficulty in getting sufficient suitable material for our anatomical schools. Is it not time that some of us, at all events when we should not offend the sentimental susceptibilities of those we leave behind, left our own corpora for such purpose? If, after the catastrophic event of death, our egos know what is going on here, is there really anything unpleasant in the thought that light-hearted students will be gathered round? Is it not rather a pleasing thought that some discovery may be made which will benefit mankind or, at least, that we are making medical study easier? The cremated ashes could, of course, be collected and buried later. I am not advocating what I do not suggest for myself, and have left instructions in my will making such an offer to the Oxford Medical School.—I am, etc.,

RICHARD WHITTINGTON.

Hove, Feb. 16th.

Medico-Legal.

ACTION AGAINST A HOSPITAL.

LAVELLE *v.* GLASGOW ROYAL INFIRMARY.

ON November 26th, 1929, in the Second Division of the Court of Session at Edinburgh (Lords Ormidale, Hunter, and Anderson), an action raised by Mrs. Mary Anderson or Lavelle in the Sheriff Court at Glasgow against the Glasgow Royal Infirmary for damages of £500 for personal injury was dismissed.

In this action the pursuer alleged, *inter alia*, that while she was being treated for neuritis at the Infirmary in December, 1928, she was injured by over-exposure to ultra-violet rays through the negligence of a nurse employed by the defenders, and for whose carelessness they were responsible. The defenders maintained that the administration of ray treatment by a nurse, acting under the instructions of an infirmary doctor, was not a "purely ministerial or administrative duty," and that they were not responsible for the exercise of her professional care and skill.

In giving his judgement Lord Ormidale said[1]:

"The infirmary is not a statutory body, but a voluntary hospital open to all and sundry who elect to seek its aid, and the limits of legal responsibility attaching to the governing body of such an institution are confined to the due and careful selection by them of a competent staff and the supply of fit and proper apparatus and appliances, 'and do not'—I here quote from the opinion of Lord Dundas in *Foote* v. *Directors of Greenock Hospital* (1912, S.C., p. 72)—'extend to the supervision by them of the professional actings of members of the staff, or to any sort of guarantee that these will be performed with skill and care in any given case.' . . . It is true that the case of *Foote* had to do with alleged maltreatment at the hands of a surgeon or doctor but the case of *Hillyer* v. *Governors of St. Bartholomew's Hospital* (1909, 2 K.B., 820) was approved and followed . . . and it was held that the nurses and other attendants assisting at an operation cease for the time being to be the servants of the authority inasmuch as they take their orders during that period from the operating surgeon alone and not from the hospital authorities. The law of *Hillyer's* case, in my opinion, applies to the present case. I am unable to hold that any material distinction can be drawn between the position of a nurse in relation to a surgeon performing an operation and that of a nurse in relation to a doctor charged with the curative treatment of a patient by ultra-violet rays. It is to the directions of the latter that the nurse is bound to conform, and it is her professional skill that is called in aid. . . There was no averment that the defenders had failed to exercise due care in the selection of their nurses."

Lords Hunter and Anderson also delivered judgements dismissing the appeal.

RECOVERY OF PROFESSIONAL FEES.

ON February 18th, at the West London County Court, Judge Hargreaves gave judgement, reserved from the last hearing on February 3rd, for Dr. Murray Leslie of Knightsbridge, for £22 11s. 6d. in a claim against Mr Charles Taylor, described as managing director and proprietor of the Basil Street Hotel, Knightsbridge, for £53 as balance due for professional services. Five guineas were deducted in respect of attendances, and the claim for professional visits paid to employees of the defendant was not allowed.

According to the plaintiff, a difficult and dangerous operation had been performed on the defendant, who had left a nursing home after three weeks against his orders. Had the defendant died in such circumstances the plaintiff would have been liable to a charge of manslaughter in addition to losing his professional reputation. The defendant, in evidence, alleged that Dr. Leslie was called in without his knowledge or authority, and that the value of his services was considerably overrated.

Judge Hargreaves said that the difficult point in the case was the question of attendances made by the plaintiff after relations between the parties had ceased to be good. Speaking generally, the qualified evidence was to the effect that the operation had been a serious one, not so much on account of the operation itself, but on account of the general health of the defendant. While expressing the desire that the plaintiff should not call so frequently, the defendant did not terminate the contract, but

[1] *Scots Law Times*, January 11th, 1930.

said he was willing to risk the consequences of reduced attendances.

"It must be for the doctor to decide how often he ought to see a patient. The fact that these two did not personally 'get on,' and the fact that Mr. Taylor did not like Dr. Leslie attending him so often, does not really come into the matter so long as the relationship of the patient and the doctor continues. It was not the doctor who chose the patient, but the patient who chose the doctor. To my mind the expression used by Mr. Taylor on March 7th after the operation goes so far as to make clear that he was willing to take the risk of fewer attendances. The doctor could then, to cover himself, have written a letter to say that the risk of less frequent attendance must be borne by the patient. I have come to the conclusion that after March 7th attendances might have been fewer than they were."

The Services.

DEATHS IN THE SERVICES.

Surgeon Lieut. Commander Francis Woora, R.N. (ret.), died, after a long illness, at Chelstow Cottage, Torquay, on January 29th. He was educated at St. Mary's and at the London Hospital, and took the Edinburgh double qualification in 1882. Entering the navy in the same year, he became staff surgeon on August 28th, 1894, and retired on February 19th, 1895. He had since held the post of Admiralty recruiting officer and surgeon and agent at Torquay, and was on the list of emergency officers, liable to recall to duty, with the rank of surgeon lieutenant commander.

Surg. Lieut. Commander Archibald Primrose Anderson-Stuart, R.N., died at Culross, Deal, on February 16th, aged 34. He was the eldest son of the late Sir Thomas Anderson-Stuart of Sydney, and was educated in the University of that city, where he graduated as M.B. and Ch.B. in 1921. He entered the navy as surgeon lieutenant on June 15th, 1923, and was promoted to surgeon lieutenant commander on June 15th, 1929. He first served in H.M.S. *Southampton*, the flagship of Admiral Sir Herbert Richmond in the East Indies; in December, 1925, he was appointed to the Royal Marine Infirmary, Deal, and in September, 1928, to H.M.S. *Benbow* in the Atlantic Fleet, and subsequently to H.M.S. *Caradoc* on the West Indian Station.

Lieut.-Colonel Ernest Shaw Clark, R.A.M.C. (ret.), of Shalimar, Cuckfield, Sussex, died in Queen Alexandra's Military Hospital, Millbank, on February 15th, aged 64. He was born on September 24th, 1865, and was educated at Edinburgh, where he graduated as M.B. and C.M. in 1889. Entering the R.A.M.C. as surgeon lieutenant on January 29th, 1894, he became lieutenant-colonel in the long war promotion list of March 1st, 1915, and retired on September 21st, 1920. He served on the North-West Frontier of India in the Mohmand campaign of 1898, receiving the frontier medal with a clasp, and also in the great war of 1914-18.

Lieut.-Colonel George Coutts, R.A.M.C. (ret.), died at Golders Green on January 18th, aged 75. He was born on November 8th, 1854, and was educated at Aberdeen, where he graduated, with honours, as M.B. and C.M. in 1879. Entering the army as surgeon on February 5th, 1881, he became lieutenant-colonel after twenty years' service, and retired on February 5th, 1908. After retirement he was employed for some time at Chichester. He served in the Chitral campaign of 1895, with the relief force, when he was mentioned in dispatches in the *London Gazette* of November 15th, 1895, and received the frontier medal with a clasp; also in the South African war, in 1899-1901, when he took part in the advance on Kimberley, including the action at Magersfontein, and in operations in the Transvaal and the Orange River Colony, including the actions at Lindley, Bethlehem, and Wittebergen, and received the Queen's medal with three clasps.

Lieut.-Colonel Percival Davidson, C.M.G., D.S.O., R.A.M.C. (ret.), died suddenly in Switzerland on January 28th, aged 55. He was born on April 16th, 1874, the son of the late Percival Davidson of Newcastle-on-Tyne, and was educated at the medical school of that city, graduating M.B. and B.S. of Durham University in 1895. After filling the posts of house-physician and house-surgeon at the Royal Infirmary, Newcastle, he went to South Africa as a captain in the 5th Battalion of Imperial Yeomanry, and served in operations in the Transvaal, Orange River Colony, and Cape Colony; he was mentioned in dispatches in the *London Gazette* of September 10th, 1901, and received the Queen's medal with four clasps, the D.S.O. in 1900, and the Freedom of the City of Newcastle-on-Tyne in 1901. After serving as a civil surgeon for a year and a half, he took a commission as lieutenant in the R.A.M.C. on September 1st, 1902, attained the rank of major on June 1st, 1914, got a brevet as lieutenant-colonel on June 2nd, 1918, and became substantive lieutenant-colonel on June 21st, 1924, retiring on April 16th, 1929. He served throughout the war of 1914-18, when he was A.D.M.S. in the First Army and at General Headquarters, was thrice mentioned in dispatches, in the *London Gazette* of June 22nd, 1915, January 1st, 1916, and May 25th, 1918, received a brevet as lieutenant-colonel, and the C.M.G. as well as the Portuguese Order of the Aviz.

Lieut.-Colonel James Macartney, R.A.M.C. (ret.), died at Brighton on January 27th, aged 88. He was born in Dublin on January 26th, 1842, and graduated as M.D. in the Queen's University, Ireland, in 1865. Entering the army as assistant surgeon on October 2nd, 1866, he attained the rank of brigade surgeon lieutenant-colonel on December 15th, 1892, went on half pay on September 8th, 1894, was restored to full pay on November 12th, 1895, and retired on January 26th, 1897. After retirement he was employed for some time at Canterbury. He served in the South African war of 1877-78, in the Kaffir campaign, was mentioned in dispatches in the *London Gazette* of February 26th, 1878, and received the medal with a clasp. In the old regimental days he served in the Rifle Brigade.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

PROFESSOR H. R. DEAN, M.D., Master of Trinity Hall, has been appointed to represent the University at the jubilee of the foundation of the Victoria University of Manchester and the eightieth anniversary of Owens College on May 23rd.

Dr. R. Williamson has been appointed University demonstrator in pathology for three years.

At a congregation held on February 21st the following medical degrees were conferred:

M.D.—N. E. Chadwick, J. A. Struthers.
M.B., B.CHIR.—J. F. V. Lart, T. R. Stevens.
M.B.—J. H. L. Easton.
B.CHIR.—B. Wright.

UNIVERSITY OF LONDON.

A COURSE of two lectures on the growth and developmental mechanics of bone will be given at University College, Gower Street, W.C.1, by Dr. J. C. Brash, Professor of Anatomy and Dean of the Faculty of Medicine in the University of Birmingham, on March 11th and 13th at 5 p.m. The chair at the first lecture will be taken by Professor G. Elliot Smith. Admission to the lectures, which will be illustrated by specimens and lantern slides, is free; they are addressed to students of the University and others interested in the subject.

UNIVERSITY OF MANCHESTER.

DR. WILLIAM H. LANG, F.R.S., Barker Professor of Cryptogamic Botany in the University of Manchester, has been appointed a Pro-Vice-Chancellor, in succession to Professor John S. B. Stopford, whose term of office has expired.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

Museum Demonstrations.

THE spring course of demonstrations of specimens in the Museum will commence on Monday, March 3rd, when Mr. C. E. Shattock will discuss affections of lymphatic glands. On March 7th Mr. T. B. Layton will deal with the rhinological anatomy of the naso-frontal duct and the hiatus semilunaris. On March 10th the demonstration will be on affections of joints by Mr. Shattock, and Sir Frank Colyer will demonstrate John Hunter's specimens of the teeth on March 14th. Mr. Shattock will discuss diverticula on March 17th, and Sir Frank Colyer will conclude the course on March 21st by demonstrating specimens illustrating dento-alveolar abscess and dental cyst. The demonstrations will be given in the theatre of the College, Lincoln's Inn Fields, W.C., at 5 p.m., on the dates mentioned, with the exception of that on March 7th, which will be held at 2.45 p.m. They are open to advanced students and medical practitioners.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY.—T. Chandrasekharan, B. T. W. Harvey, C. B. Jennings, T. Singh, P. Somasunder, A. L. Thomas, H. Whitby.

MEDICINE.—B. T. W. Harvey, W. A. R. Mailer, I. W. H. Mansfield, J. E. Moody, S. Ramadas, D. Ram Annamalai.

FORENSIC MEDICINE.—M. Asaad, L. Banszky, K. W. Bruce, G. P. Charles, L. P. Clarke, V. J. H. Coidan, H. W. E. Dickey, I. F. W. Edwards, A. R. Madden, W. A. R. Mailer, I. W. H. Mansfield, B. G. Nair, C. Skinner, P. Wade.

MIDWIFERY.—R. P. Davies, R. Frankling, B. T. W. Harvey, C. B. Jennings, N. I. Kronengberg, F. G. Leckam, M. Naylor, D. M. Nightingale, L. Sachs, P. Wade.

The diploma of the Society has been granted to Messrs. C. B. Jennings, W. A. R. Mailer, I. W. H. Mansfield, J. E. Moody, M. Naylor, S. Ramadas, D. Ram Annamalai, P. Somasunder, H. Whitby.

Obituary.

ALFRED HERBERT TUBBY, C.B., C.M.G., M.S., F.R.C.S.,

Consulting Surgeon to the Westminster Hospital, the Royal National Orthopaedic Hospital, and the Evelina Hospital for Children.

WE regret to record the death of Mr. A. H. Tubby, the well-known orthopaedic surgeon, which took place on February 23rd at Hastings, in his sixty-eighth year.

Alfred Henry Tubby received his general education at Christ's Hospital, where he was a schoolfellow of one who was in later life to be his colleague on the honorary staff of the Orthopaedic Hospital, Dr. F. J. Smith, known and beloved at the London Hospital as "F. J." From the Blue-coat School Tubby proceeded to Guy's Hospital Medical School. He became M.R.C.S.Eng. in 1884, and L.R.C.P.Lond. in 1886. He won the gold medal in medicine, and took honours in forensic medicine, anatomy, and materia medica in the examination for the degree of M.B. at the University of London, and the gold medal in surgery in the examination for B.S. in 1887. In the same year he became F.R.C.S.Eng. After graduating he studied abroad at Halle and at Leipzig. In 1891 he was elected surgeon to the National Orthopaedic Hospital (since incorporated with the Royal Orthopaedic Hospital). He was elected assistant surgeon to the Westminster Hospital in 1894, and four years later became full surgeon. In later years he was made honorary consulting surgeon to his old school, of which he was also a governor and an almoner.

His interest in orthopaedics dated from the time of his appointment on the staff of the Orthopaedic Hospital, and a wider interest in the diseases of children manifested itself in his connexion with the Evelina Hospital for Sick Children, and in his co-operation with Mr. S. Stephenson in the foundation of the Society for the Study of Disease in Children. He was president for a term of the Section of the Royal Society of Medicine devoted to children's diseases. His orthopaedic work led him to take a great part in founding the British Orthopaedic Society, of which he was for some time secretary, but which was wound up after a few years' existence. When the present flourishing British Orthopaedic Association was founded in 1918 he was one of the original members, but took little part in its proceedings at any time. In general surgery he did not make much mark, although he wrote on appendicitis and was president of the Hunterian Society for a term. He was made a corresponding member of the American Orthopaedic Association and of various other foreign societies. He was a member of the British Medical Association for many years, and at the time of his death was an associate member of the Hastings Division. He was secretary of the Section of Diseases of Children at the meeting at Portsmouth in 1899, and president of the same Section in 1907 at Exeter. He was president of the joint Section of Orthopaedics and Diseases of Children in 1921 at the meeting at Newcastle-on-Tyne.

Before the war Tubby had joined the medical staff of the Territorial Force, and on mobilization he was called up for service as lieutenant-colonel at the Fourth London General Hospital. He was seconded in 1915 for service as consulting surgeon to the British Mediterranean Expeditionary Force, with the rank of temporary colonel on the Army Medical Staff, and later to the Egyptian Expeditionary Force, serving much of his time abroad at Alexandria. His services were thrice commended in dispatches, and he was awarded the C.B. and C.M.G.

Tubby was the author of a number of books and papers not only upon surgical, but upon other subjects of more general interest, such as sport and archaeology. He took a prominent part in the expansion of the scope of orthopaedic surgery which was in full movement about the end of the last century generally, and particularly in making known and elaborating the treatment of the paralyses following anterior poliomyelitis by means of tendon transplantation, which had been begun by Oskar Vulpius of Heidelberg in 1897, and his first book, written in collaboration with Mr. (now Sir) Robert Jones was entitled *Modern Methods in the Surgery of Paralysis*, which appeared in 1903. He was, however, probably best known by his book *Deformities, a Treatise on Orthopaedic Surgery*, which was published in 1906, and which was held by many to be the best work in the language then existing. It had an immediate success, so that a second edition in two volumes was called for in 1912. This book, unlike most works on orthopaedics published in Great Britain before that time, included not only the deformities, but the active diseases of joints, and especially tuberculosis. In the preface he freely acknowledged the valuable services rendered by Mr. Vincent Moxey, M.R.C.S., who did much of the spade work necessary in the preparation of the book. He wrote "Reminiscences of chamois hunting" in the *Alpine Journal*, and the article "Chamois hunting" in *British Sports and Sportsmen*.

Active in mind and body, Tubby worked hard at his profession and his pastimes. He became a member of the Alpine Club, and took great pleasure in the use of the sporting rifle, whether the quarry were chamois, wild boar, or deer. He was also a keen fisherman. Even before the war his interest in hospital work was waning, and his private practice and love of sport engrossed his energies more and more, and during the war, when he was serving at Alexandria, he found time to spare for archaeological exploration, for which work he was made a Fellow of the Society of Antiquaries. He was able to finish up his military service with a trip to Palestine, which furnished him with the material for a book of a popular character, *A Consulting Surgeon in the Near East*. His last published work we believe to be a small book, *The Advance of Orthopaedic Surgery*, made up of six articles which had appeared serially in 1925. For the past four or five years he had retired from practice and took up his abode at Hastings. His death ensued on a month's illness. He leaves a widow and a married daughter.

Only four months ago we had to lament the death of Mr. T. H. Openshaw, and now that of Mr. Tubby reminds us of the parallelism in some respects of the careers of these two men. Both were general hospital surgeons. They were contemporaries on the staff of the Orthopaedic Hospital, they took part together in the formation of the Orthopaedic Section of the Royal Society of Medicine, and in the formation of two orthopaedic societies, and each held at one time the office of president of the Hunterian Society. They held similar offices at different times in the British Medical Association. Each held the rank of colonel on the Army Medical Staff and the office of consulting surgeon. Both, moreover, were fishermen and sportsmen. Each of them held office in a city company for Openshaw was

Master of the Shipwrights, and Tubby Prime-Warden of the Blacksmiths' Company, a craft more appropriate to an orthopaedic surgeon than that of a shipwright. Thus their friendly rivalry persisted for nearly forty years, and their careers ended within a few months of each other.

A former colleague sends the following appreciation:

Colonel Tubby (as since the war he preferred to be called) was widely known as an authority on the treatment of deformities. He was even better known on the Continent and in America than in this country, and his clientele extended to all lands. Although he recognized, and pointed out in his classic work on deformities, the limitations of the specialty that claimed the title "orthopaedics," yet he himself did not a little to begin that spreading of its borders which has driven them in recent years almost to the horizon. Whilst, on the one hand, he was extremely facile in the devising and exploitation of mechanical apparatus, he was, on the other, a ready and safe operator. He was very successful with the bloodless reduction of congenital dislocation of the hip, but by no means behind in the bold use of open operation. His tendon transplantations, nerve grafts, and neoarthroses were among the earliest and certainly not the least successful. Part of his success was due to the persistence and care with which he followed up all his patients, and to the practical interest he took in the direction and supervision of massage, remedial exercises, and occupational training. He inspired all connected with a case—parents, colleagues, assistants, and the patient above all—with a hopeful appreciation of progress towards ultimate recovery of some sort. His book on deformities very soon became a standard work, and in its latest form was a mine of experience, well sorted, which established it in a position from which other books, more recently published, will displace it with difficulty. He took a great deal of trouble over his lectures, and was, when he had time to spare, an illuminating teacher. In private life he had many interests—climbing, shooting, fishing, archaeology, and history generally. He possessed a most retentive memory, and had a happy faculty of anecdotal illustration which made him, as the general host of others with similar interests, a most entertaining conversationalist. His war work was almost entirely in the East. Soon after his return from Egypt he resigned his hospital appointments, but continued a certain amount of private practice until within the last year or two.

JAMIESON B. HURRY, M.D.

WE regret to report the death at Bournemouth, on February 13th, of Dr. Jamieson B. Hurry, at the age of 72. Dr. Hurry was for many years a leading member of the medical profession in Reading, and became widely known for his researches into the history of its ancient abbey.

Jamieson Boyd Hurry received his medical education at Cambridge and St. Bartholomew's Hospital. In 1882 he graduated M.B.Camb., and obtained the diploma M.R.C.S. Three years later he proceeded M.D., having become D.P.H., and in 1890 he graduated B.Ch. He then travelled for a year as ship surgeon, visiting in turn South America, Australia, and India; he was able to gratify his intense love of travel in later years by frequent foreign tours, including North America, Egypt, Morocco, and almost every European country, interesting himself in Continental medical schools, in international social questions, and especially in tropical and economic botany.

In 1885 he joined the late Mr. George May, F.R.C.S., in Reading, and practised for over forty years. At the request of the New Sydenham Society he translated Spiegelberg's textbook of midwifery. During this period he was an active member of the Reading Pathological Society and became deeply impressed with the social and professional value of medical societies. He wrote *A History of the Reading Pathological Society*, and afterwards *The Ideals and Organization of a Medical Society*, which has been in wide request by the officers of medical societies at home and abroad. He published six volumes on the subject of Reading Abbey, one of the great Benedictine monasteries of this country, and of which for many years he was the recognized cicerone. His devotion to the Abbey was further revealed by various substantial gifts to the town—for example, a noble memorial cross in honour of the founder, King Henry Beauclerc, and three memorial tablets which adorn the ancient chapter house. Every Whit Monday he used to conduct a large party of his fellow-townsmen through the ruins of the Abbey, when the world-famous canon "Sumer is icumen in," written down at the Abbey *circa* 1240, was sung. Perhaps his most valuable gift to Reading was a series of ten uniform historical oil paintings illustrating the history of the Abbey, most of which have been exhibited at the Royal Academy, and which now hang in the Reading Municipal Art Gallery. This series of pictures, each accompanied by full historical notes, was designed by the donor to stimulate civic pride and local patriotism in Reading.

Another subject which interested him, from his student days at St. Bartholomew's Hospital down to the last days of life, was the influence of the "vicious circle" process, both in individual and in social pathology. He wrote two monographs, *Vicious Circles in Disease* (third edition, 1919) and *Poverty and its Vicious Circles* (second edition, 1921); the former has been translated into French, Spanish, and Italian, and the latter into Japanese, French, and Italian. More than thirty original articles on this subject have been published, several in this *Journal*. This copious literature has done much to emphasize the prevalence of *circuli virtuosi* and *circuli vitiosi* in pathology and sociology, and has led to the widespread recognition of the importance of this circular process.

During later years Dr. Hurry devoted much time to economic botany, and established the well-known educational garden at his home in Reading. Here were assembled from all parts of the world numerous tropical and economic plants, more especially such as yield food, fibre, dyes, or medicine for the service of man, tender plants being housed in a series of hothouses. Close by, in a museum, were exhibited many of the products derived from the plants growing in the garden and conservatories. By this means the plant and its economic product could be studied side by side, and this practical method of studying economic botany attracted large numbers of visitors from far and near. In 1926, owing to impaired health, Dr. Hurry and his family removed to Bournemouth.

J. M. DUNCAN SCOTT, M.A., M.D., PH.D.,

Professor of Physiology, University of Saskatchewan.

JAMES MATTHEWS DUNCAN SCOTT was born in Melrose, Roxburghshire, Scotland, on February 6th, 1889; his father, a medical practitioner, died when his son was only 5 years old. At the age of 16 he entered the University of St. Andrews with a bursary from Dollar Academy. In 1908 he graduated M.A., and was medallist in the classes of mathematics and botany as well as prizeman in chemistry and anatomy. In the class of physiology Scott attained the first place in the honours list, being far ahead of the man who came next to him.

Leaving St. Andrews in 1908, Scott went to Edinburgh University to complete his medical studies. There he did conspicuously well, for in Sir Edward Schafer's department he won the medal in physiology and in experimental physiology, as well as the McKenzie prize in anatomy. He was also medallist in the class of pathology taught by the extramural lecturer, Dr. (now Professor) James Miller. In the University department of anatomy Scott acted as prosector to the late Professor Cunningham. While still a medical student Duncan Scott was asked to return to St. Andrews for a session to conduct the class in histology during the absence of Professor Herring on sick leave. In 1912 he graduated M.B., Ch.B. with honours at Edinburgh University. Between that time and the outbreak of the great war Scott was successively house-surgeon at the Royal Infirmary, Dundee, at the Edinburgh Royal Infirmary, and assistant medical officer on the Consolidated Gold Fields, where he had charge of two native hospitals of 300 beds. In May, 1914, he found himself district surgeon at Lomagundi, Southern Rhodesia, in charge of a European and of a native hospital. On the outbreak of the war he went out to South-West Africa with the 1st Rhodesian Regiment, and there dealt successfully with

the problem of a poisoned water supply. After the end of the campaign in South Africa he went to the Mediterranean on the South African hospital ship *Ebani*, where he had responsible duties, and where on one occasion, when the ship was stopped by an enemy submarine, it fell to him to take command of the sick and make all preparations to abandon the ship.

In February, 1916, Scott was sent out to Cairo, where he was in turn senior medical officer of the Kasr-el-Nil Barracks, and of the Abbassia Camp, where he had command of 20,000 men. Later he was at Salonica, where he did valuable antimalarial work, but whence, unfortunately, he was invalided home with malaria. He had, in addition, at an earlier date, received a severe wound in the head. After a delay caused by convalescence he went to Cambridge to study for the D.P.H., and, as a member of King's College, he began research work in physiology under Professor Barcroft. As the outcome of this he wrote his M.D.Ed. thesis (1920), "The length of life of the red blood corpuscle," and published five papers, all dealing with the biochemistry and histology of blood. While at Cambridge he demonstrated for the late Professor Langley in histology and experimental physiology, as well as in biochemistry. In April, 1921, he was appointed to the John Lucas Walker studentship, and from October, 1920, to December, 1921, he held a part-time grant from the Medical Research Council.

While at Cambridge Scott made experimental investigations into the physiology of the centres in the medulla oblongata, more particularly the vasomotor centre. His first paper, written in collaboration with Dr. Ff. Roberts, was entitled "Localization of vasomotor centre"; the second, of which he was the sole author, was called "The part played by the ala cinerea in vasomotor reflexes." In 1925 he was appointed to a British Medical Association Research Scholarship, and in the same year published in the *British Medical Journal* a paper on vagal vascular reflexes. Concluding his stay at Cambridge by graduating Ph.D. in 1924, Scott was appointed demonstrator of physiology under Professor Lovatt Evans, then at St. Bartholomew's Hospital. Later he became lecturer and senior demonstrator in physiology.

Duncan Scott was what is sometimes called a "born teacher"; he had the instinct for imparting knowledge clearly, concisely, and picturesquely. He was fully aware of the necessity of arousing the student's interest in the subject if he was to make any real use of the knowledge given him. Like most successful teachers he had been through the drudgery of conducting revision or "coach" classes for the F.R.C.S. and other examinations. In the winter of 1924–25 he was asked to give a short course of advanced lectures at University College on his researches into the bulbar centres. Professor Lovatt Evans has testified with emphasis to his organizing ability, capacity as a teacher, pleasant personality, and independent manner of thinking. In the summer of 1926 Dr. Scott was appointed professor of physiology in the University of Saskatchewan, Saskatoon, Canada. Here he had ample opportunity for exercising his teaching powers and his organizing capacity. A brilliant future seemed to be before him, but it was destined never to be his. On January 26th he seemed quite well, on the 27th he became unconscious, and on the 28th he died from meningitis. He is survived by his widow and two young children.

D. F. F.-H.

S. F. St. D. GREEN, C.B., C.B.E., M.D.,

Major-General, late R.A.M.C. (ret.).

WE regret to announce the death of Major-General Sebert F. St. D. Green, on February 5th, in Queen Alexandra's Military Hospital, Millbank.

Sebert Francis St. Davids Green was born in 1868, and received his medical education at the University of Durham and St. Bartholomew's Hospital. He obtained the diplomas M.R.C.S., L.R.C.P. in 1892, and graduated M.B.Durham in 1910, proceeding M.D. two years later. He entered the army as a surgeon lieutenant in 1894, and attained administrative rank as colonel in 1917. He was promoted to the rank of major-general in 1923, and retired four years later. He was in charge of the Louise Margaret Hospital at Aldershot from 1907 to 1912. In 1914, when the war began, he was serving in India; he went to France with the Indian Expeditionary Force in command of the Rawal Pindi British General Hospital, which he took to Mesopotamia in December, 1915. In July, 1916, he was appointed A.D.M.S. at Amara, and in May, 1917, A.D.M.S. at the base in Mesopotamia. In September, 1918, he was appointed to the command of the Prince of Wales Hospital for Officers at Marylebone. In 1920 he went to the Irish Command as A.D.M.S. of the 5th Division; from 1921 to 1923 he was D.D.M.S. of the Scottish Command; and on promotion to major-general was posted as D.D.M.S. of the Western Command in India. He held that post for four years, except for four months in 1927, when he acted as Director of Medical Services in India. During the war he was thrice mentioned in dispatches—in the *London Gazette* of October 19th, 1916, March 12th, 1918, and August 27th, 1918, and received the C.B.E. In 1924 he was appointed Honorary Physician to the King, and in 1925 he received the C.B. In 1896 he married Evelyn Caroline Marion, daughter of Major Hely, J.P., of Foulk's Court, Kilkenny, who died in 1927; he leaves three sons and two daughters.

We are indebted to Major-General Sir S. G. GUISE-MOORES, K.C.B., for the following appreciation.

Coming from stock which had sent many of its sons into the service of the State—the Church, the Army, and the Navy—and holding as he did an abiding conviction that they had served it well and with distinction, it was only natural that young Green, on choosing the profession of medicine, should, when full qualification came and opportunity offered, decide to follow the drum. A wanderlust that an army life could abundantly satisfy, and the spirit of adventure that it could freely give, appealed to one of his kind. He joined the R.A.M.C., and early went East of Suez. My foremost recollection of him was as staff surgeon at Lucknow in 1897. The Families Hospital there fixed his ambition in one direction, and laid the foundation of what was later to become a unique and extended practical knowledge and experience of disorders incidental to women and children. This preparation and active interest led, on his return home, to the charge of the Louise Margaret Hospital at Aldershot, then in process of reformation. He found there full scope for his particular talents in the work of the wards and in the operating theatre. He left to his successor, when the hour arrived, a fine reputation, and a hospital replete with all the requirements of a well-found and up-to-date institution. His tenure at Aldershot was extended beyond the normal period, for it was soon recognized that his gifts as a teacher brought continued successes at the examinations of the Central Midwives Board—successes which, as time advanced, made it more and more difficult to find accommodation for the many applicants desiring to benefit by his lectures and classes of instruction. As a surgeon and diagnostician in particular he had then made his mark, and his name will ever be gratefully remembered and honoured for his abilities, courtesies, and steadfastness. Sebert Green always gave a foremost place in his thoughts and actions to results that would enhance the professional credit of the corps to which he was proud to belong, and there is no doubt that his life's work constitutes a fine example of purposeful rectitude in this and all respects.

DR. JAMES SUTHERLAND EDWARDS, who died from heart failure on February 8th, at Perth, was born in 1884, and graduated M.B., Ch.B. at Edinburgh with first-class honours in 1906. After holding the posts of house-physician under the late Professor Greenfield in the Edinburgh Royal Infirmary and house-surgeon in the Dumfries Royal Infirmary, he practised for a time at Bridge of Earn. He later moved to Perth, and was appointed visiting physician to the Perth Royal Infirmary. He was also medical officer to the Post Office and to Perth Penitentiary, bacteriologist to the county fever hospital, and parochial medical officer for Rhynd and Forgandenny. His wife died four years ago; he leaves three children. He was a member of the British Medical Association.

DR. FREDERICK RICHARD HALL, who died on January 28th, on his thirty-first birthday, received his medical education at St. Thomas's Hospital, and, being of exceptional intellectual capacity, passed the final examinations before coming of age; he had therefore to wait before obtaining diplomas, and was admitted surgeon probationer in the Royal Navy during the war. He subsequently made two journeys to the Far East, and received the diplomas M.R.C.S., L.R.C.P. in 1920. He was for some time surgeon to the Ministry of Pensions Hospital in Richmond. After a short residence in Harrogate, he joined Dr. W. R. Higgins in practice in Louth, Lincolnshire, and was appointed honorary surgeon to the Louth Hospital. Dr. Hall was a member of the British Medical Association. He leaves a widow and three daughters.

DR. DONALD HENRY HUTCHINSON, who died on February 1st, at the age of 56, received his medical education at the University of Edinburgh, where he graduated M.B., C.M. in 1896, proceeding M.D. two years later. He began to practise in Lowestoft some thirty years ago, and was surgeon to the Lowestoft and North Suffolk Hospital and medical officer of the Lowestoft Convalescent Home. In addition to carrying on a large general practice, he became prominent in the borough for his public-spirited activities in connexion with sport and the Y.M.C.A.; he was appointed a justice of the peace in 1916. During the war he held a commission in the R.A.M.C. and served in Mesopotamia. He was one of the founders and the first president of the Lowestoft Literary and Scientific Society, and was for a long period officially connected with St. John's Church. He was for many years a member of the Lowestoft Education Committee, and was appointed chairman of the Joint Higher Education Committee in 1921, which office he held until his death. He was a member of the British Medical Association, and was chairman of the North Suffolk Division from 1920 to 1921. He leaves a widow and two sons. A colleague writes: Dr. Hutchinson's scientific attainments were of a very high order, both as a physician and surgeon, and also as a naturalist. He was an exceptionally successful and practical surgeon, exhibiting manual dexterity of a very high degree. Among his hobbies were cabinet making and the manufacture of scientific instruments.

DR. JOHN KERWICK, who died on January 27th, was born in 1870, and was educated at the Middlesex Hospital and the Royal Dental Hospital. He obtained the diploma L.D.S.R.C.S. in 1891, and the M.R.C.S., L.R.C.P. three years later. After holding the post of house-surgeon at the Dental Hospital he succeeded to the practice in Carlisle which had been founded by his father, and carried on by his uncle. He was dental surgeon to the Cumberland Infirmary from 1899 to 1911, and again during the war; he was also honorary dental surgeon to the Border Home for Incurables. He was an active member of the North of England Odontological Society and of the British Dental Association, a Fellow of the Royal Society of Medicine, and a past-president of the Carlisle Microscopical Society. During the latter part of his life he resided in the village of Dalston. The countryside always appealed to him; he was an enthusiastic gardener, and he had many friends among the agricultural community. He contributed papers to dental journals, and was the editor of the *Transactions* of the North of England Odontological Society. He leaves a widow and three sons.

The following well-known foreign medical men have recently died: Dr. BIEDERMANN, formerly professor of physiology at Jena, and author of a work on electrophysiology; Professor KARL SVEHLA, head of the Czech children's clinic at Prague; Professor BEUTTNER, head of the obstetrical clinic at Geneva, aged 63; Dr. JULIAN CORONEL, professor of clinical medicine in Ecuador; Dr. RAOUL BRUNON, honorary director of the medical school of Rouen, and corresponding member of the Académie de Médecine, aged 75; Dr. ALBERT KÖNIG, an eminent hygienist of Frankfort; and Dr. KAMINSKI, director of the civil health service of Bucarest.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THIS week the House of Commons discussed supplementary estimates for the Royal Parks and for Colonial Services. Three days were spent in committee on the Coal Mines Bill. The Mental Treatment Bill and the Road Traffic Bill were before Standing Committees.

On February 25th the Parliamentary Medical Committee met at the House of Commons and received a deputation from the British Medical Association. Dr. Fremantle was in the chair. The first subject raised by the deputation concerned medical men who, under the new Local Government Act, find themselves both members of local authorities and the servants of those authorities. The deputation and the committee accepted the principle that medical men retaining posts under public authorities must be disqualified from membership of those bodies. Attention was, however, drawn to the injustice to doctors who, preferring to keep their seats on local bodies, resigned their salaried posts. It was pointed out that a man who took this course after paying for many years to a superannuation fund would lose his contributions. The conference arranged that the British Medical Association should draft a one-clause bill to provide that all such contributions should be returnable. When this has been drafted the Parliamentary Medical Committee will consider it.

Many questions arose from the Mental Treatment Bill. The first discussed was the better safeguarding of doctors who recommend voluntary treatment or take any part in dealing with insanity. No definite decision was taken on the manner in which the bill could be strengthened. Neither was any recommendation made for a phrase to be substituted for "not capable of volition" in Clause 5 of the bill. A long definition put forward by the British Medical Association did not secure the full approval of the Parliamentary Committee. The meeting desired to secure minor improvements in the position and constitution of the Board of Control. One was that there should be three types of members, and that the persons who did the visiting in the country should not be Assistant Commissioners but full Commissioners, though not members of the small central board.

The conference discussed the Chiropodists Bill, and decided that chiropodists did not merit legal registration, as they were only qualified to deal with some foot troubles. On the Road Traffic Bill the Association's representatives claimed that doctors attending road casualties should have a legally enforceable fee. There were varying views on this, but no decision; nor was any decision arrived at on the claim of voluntary hospitals to a share of the insurance paid to injured persons whom they treat. It was pointed out that the bill permits the Minister to hold an inquiry after any road accident. The Association's delegates were of opinion that he should have power to investigate the physical and mental condition of the drivers concerned.

Dr. Brackenbury spoke for the British Medical Association on the position of doctors employed by local authorities, Dr. Langdon-Down on mental treatment, and Dr. J. W. Bone on the Road Traffic Bill and other issues.

The Parliamentary Medical Committee decided, at the same meeting, that at its next meeting, on March 11th, it would hear Sir Malcolm Delevingne on dangerous drugs, and on the work of the League of Nations for their control.

Mr. Snowden proposes to introduce the Budget on April 14th.

Road Traffic Bill.

SECOND READING.

The Road Traffic Bill was read a second time without a division by the House of Commons, on February 18th, after prolonged debate. In this, Mr. HERBERT MORRISON, Minister of Transport, explained—as stated in last week's parliamentary report—that the Government could not accept an amendment inserted by the House of Lords to ensure voluntary hospitals a share of the insurance taken out by motorists. Mr. Morrison also expounded Clause 5 of the bill, relating to the disqualification of certain persons as drivers. He said this clause made certain physical defects an absolute bar to the obtaining of a driver's licence. It also provided that a person suffering from physical defects which were not an absolute bar might obtain a general driving licence or a licence limited to the driving of an invalid carriage, or of specially adapted vehicles, if he showed the licensing authority that a general or limited licence could safely be issued to him. Clause 19 dealt with the maximum hours for the drivers of heavy motor vehicles. Clause 23 empowered the Minister to direct inquiries into all cases of accidents.

Colonel ASHLEY, formerly Minister of Transport, supported the proposal of the bill that a declaration of physical fitness and the fact that an applicant was not suffering from physical disabilities

should suffice to secure the grant of a licence. With regard to hospitals, he hoped Mr. Morrison would retain in the bill the subsection inserted by the Lords, and would make it work. There was a strain on the resources of hospitals on the great roads. When a man received money for injuries the hospital which treated him should be allowed (as proposed by the House of Lords) to get back, up to £25, the money it had expended on his nursing and doctoring. Colonel Ashley explained that he would agree to put a municipal hospital on the same footing.

Mr. WEST RUSSELL referred to road accidents resulting from drunkenness, and thought that in Clause 15 the bill did not give the public adequate protection against them. Penalties ought to apply if it were clearly proved that the man was under the influence of drink at all. They had a right to expect that any man driving a motor car on the public highway should so control himself as to be sure there was nothing to interfere with his nervous condition while he was at the wheel.

Dr. SALTER said that in 1929, though the figures had not yet *been published, in all probability over 7,000 people had been killed* in this country by the impact of motor cars, and the injured *would probably exceed 170,000.* It was estimated that yearly 20,000 people suffered concussion owing to motor accidents. A frequent after-consequence of concussion was permanent impairment of the mental faculties. That was one of the gravest aspects of the problem of the road. An army of people was appearing, who, as the result of accident, had more or less to depend on relatives or the community for their livelihood. Last year the number of people killed on the road was greater than those who lost their lives from all the notifiable diseases. More than twice as many people were killed on the roads as perished in childbirth. More were killed on the road than at their places of occupation and work. If the speed limit was abolished the number of fatalities would go up by leaps and bounds. Many of his friends believed there would be practically a 50 per cent. increase if the speed limit was abolished. Under the existing law they would, within four or five years, have 10,000 a year killed and 250,000 injured. More than two-thirds of those killed in London last year —333 out of 1,257—were pedestrians, and only 264 were occupants of vehicles. The balance was almost entirely of pedal cyclists, who were run down by vehicles. Deaths increased by 15 per cent. each year; the motor vehicles only increased by 7 per cent. That seemed to indicate that there was *growing recklessness*, or some comparable cause. He was unable to understand the callousness exhibited on the question. If a medical man produced a new vaccine which led to 7,000 deaths in one year prompt measures would be introduced to put a stop to his activities. People bought cars guaranteed to do ninety or ninety-five *miles per hour*, with the intention of using them. The dangerous driving clause of the bill would be ineffective. Clear roads did not exist in this country, and the greatest number of fatalities occurred *on roads outside* the crowded areas. At Bromley, on a three or four mile stretch of open road just outside the County of *London*, an average of two people were killed each week. In Bermondsey, where 600 trees were knocked down every year, the destruction was from motors mounting the pavements owing to excessive speed. As the congestion in London and other great towns became greater the average pace of vehicles was reduced, and the death *rate went* down. Private cars and light motors were responsible for most *of the deaths. Speed* went to the head like champagne, and if all speed limits were abolished for private cars thousands of drivers would give way to this intoxication. A speed limit should be in addition to, and not in *substitution for, the dangerous* driving clause.

Mr. LLEWELLYN JONES said that, as coroner for a Welsh county, he had investigated an increasing number of fatal accidents. Most happened to vehicles driven by men of long experience. Very rarely was a novice involved in an accident, except where he was the victim. In 75 or 80 per cent. of the cases the motorist was a man of long experience.

Sir GERVAIS RENTOUL said that in 1928, according to the Royal Commission, 29,628 of the accidents on the roads of this country were caused by non-mechanical vehicles or by pede-trians. One-eighth of the fatal accidents, and one-quarter of the non-fatal ones, were due to these; 23 per cent. of the total accidents were found to be due to the fault of pedestrians.

Mr. TINKER thought that the compensation to hospitals should not be limited to £25. They should be entitled to receive the actual cost before any money was paid to the patient.

Sir WILLIAM JOWITT, *Attorney-General, referred to Clause 15*, which deals with the offence of drunkenness in charge of a car. He said this clause ought to be made as drastic as possible. It would be monstrous if persons found guilty of drunkenness in charge of a car should not be sent to prison. The words in the bill had been suggested by Lord Buckmaster, but the Government would consider any others which were proposed.

As stated above, the bill was read a *second time.*

On February 20th the House carried a motion authorizing its consolidation, in committee, with the Omnibuses Bill. On the same date a money resolution associated with *the Road Traffic Bill* was considered.

Mental Treatment Bill.

COMMITTEE STAGE.

Consideration of the Mental Treatment Bill by a Standing Committee of the House of Commons began on February 25th, with Mr. Cecil Wilson in the chair. The sitting was occupied in examination of Clause 1, subsection (1), which ran:

Any person who is desirous of voluntarily submitting himself to treatment for mental disorder, and who makes a written application for the purpose may without a reception order be received as a voluntary boarder in an institution within the meaning of this Act, or in any hospital or nursing home approved for the purposes of this section by the Board of Control, or, with the consent of the Board, into single care.

Dr. VERNON DAVIES moved to omit the word "*mental*" *before* "disorder." He explained that he did so to free the procedure from the stigma popularly attached to mental disorder and to encourage early application for treatment. He contended that to specify "mental" was unnecessary. There was no danger of persons applying in order to get a rest, or because they suffered from other bodily ailments. A medical man would not advise his patient to apply for treatment unless there were *early* signs of mental illness. The fact that patients under the bill could apply at out-patient clinics was another safeguard. The physician there could decide whether other signs of illness were due to the brain. There were also neurological cases with no mental symptoms, which he might describe as premental. He thought these would not be covered by the bill. Dr. Vernon Davies added that he acted independently as a practitioner with many years of experience. Some of his amendments—for example, the present—were also recommended by the Royal Medico-Psychological Association, but he put it forward on his own responsibility. He gave an assurance that he and other medical men were actuated only by desire for the good of the patient.

Mr. GREENWOOD found the amendment hard to accept. It would make the clause carry very little meaning. There must be a name for mental disease, and it must be described. "Mental disorder" was the least offensive of the names which had been used to describe mental disease.

Dr. FREMANTLE regretted the Minister's *non possumus*. The proposed amendment did not widen the scope, because treatment was to be in a hospital nursing home approved for the purposes of the section—that was, for mental treatment. He wished, from his experience of health administration, to reinforce what Dr. Vernon Davies had said about the amendment. Medical superintendents of mental institutions were charged with a sense of responsibility to the public and to the public authority; in fact, that sometimes led to accusations against them of being hard and rigid towards the patient. These superintendents, banded in the Royal Medical Psychological Association, said the words of the clause would keep out early neurological cases which did not yet display mental disorder. There was no reason why such cases should be cut out.

Mr. RHYS DAVIES said the title of the bill would indicate to the patient that his treatment was to be mental. Was it necessary for a man, in order to secure treatment, to declare that he was suffering from mental disorder?

Mr. GREENWOOD: His doctor would declare.

Mr. RHYS DAVIES: The words are "*any person who is desirous* of voluntarily submitting himself." They indicate that the request must come from the patient himself.

Mr. C. WILLIAMS thought the word "disorder" was a bad word. It was difficult to see how the ordinary person could be persuaded to assert that he was suffering from "disorder," which would suggest a very serious derangement. He thought "sickness" would be a more persuasive word.

Miss LAWRENCE said there was a difficulty of drafting. If the words "mental disorder" were omitted the purposes of the section would be obscure. The Royal Commission definitely recommended that the system of voluntary boarders should be limited to those who definitely wished it. If they once said that a doctor could put a man away——

Dr. DAVIES: What do you mean by "put him away?"

Miss LAWRENCE: I use the words because I do not want to make the profession liable to ignorant attacks outside. She added that the opinion of legislators in that room was superior to that of the heads of the medical profession on a question of drafting.

Dr. MORRIS-JONES said he did not like the words "mental disorder," but thought that the committee could not exclude from the section the fact that it dealt with cases of mental illness. He thought that this latter phrase would meet all the purposes of the clause.

Mr. GREENWOOD said he was prepared to substitute the word "illness" for "disorder."

Sir BASIL PETO thought the clause would stop people from submitting themselves for treatment which would prevent mental disorder. Even the amendment suggested by the Minister would apparently rule out preventive treatment.

Mr. D. R. GRENFELL said people should be able to get treatment without confession or humiliation as quietly as they went to the dentist, free from any sense of inferiority or incompetency.

Dr. VERNON DAVIES said he objected to the word "mental." From the associations of that word the man in the street could not get away. He asked the Minister, before the report stage, to consider the substitution of "nervous" or "psychological."

Mr. GREENWOOD said the committee must face the fact that it was dealing with mental diseases. There must be a description in the bill. Members themselves were perpetuating the stigma by pretending that the sickness had no name. "Disorder" itself was an unfortunate term. To find another word in place of mental was difficult, but he would consider the matter.

The amendment was by leave withdrawn, whereupon Mr. GREENWOOD moved to delete "disorder" in order to substitute "illness."

Dr. FREMANTLE preferred the former term as covering cases which had not reached the stage of illness. Sir GEORGE BERRY concurred.

Mr. RHYS DAVIES said that to the layman "illness" implied an expectation of recovery, while "disorder" might not.

The committee then substituted the word "illness."

Dr. FREMANTLE moved to insert that the application for reception as a voluntary boarder should be made "to the person in charge of the institution into which he wishes to be received." This would be better than an application to the clerk to the authority.

Mr. GREENWOOD had no objection to such words if the committee desired. He would prefer simply "to the person in charge." That phrase would cover nursing homes and single-care cases.

Mr. KINLEY, as an amendment to Dr. Fremantle's motion, proposed to add "or to the medical officer of health for the area." He said he did so as the first step towards eliminating the Board of Control from having anything to do with the new service for the prevention of lunacy. He wanted to shut them out absolutely from the bill, and to provide in every local area an official who would be the connecting link between the new local service and the Minister in London.

Dr. MORRIS-JONES agreed with Mr. Kinley, but thought his amendment impracticable at present. Medical officers of health as such knew nothing of mental illness, which required special study.

Mr. C. WILLIAMS pointed out that Dr. Fremantle's amendment would allow a voluntary patient to choose an institution in which he had confidence.

Sir BOYD MERRIMAN asked the committee to remember the liability of those in charge of institutions. If any question were to arise afterwards about the liability of such a person, would it not be better that he was able to say, "Here is a written application addressed to me"? There was a serious necessity for these words, and he was glad the Minister had accepted them.

On Mr. Kinley's amendment Dr. FREMANTLE, as an old medical officer of health, said it would not be practicable.

Mr. GREENWOOD said the purpose of the written statement was that there should be something definite to indicate the desire for treatment. Naturally that should go to the person in charge of the institution. If a written statement were made to the medical officer of health it would have to be referred from him to an institution—an unnecessary process in, say, a threatened breakdown from persistent insomnia.

Mr. Kinley's amendment was then negatived, and "to the person in charge" was inserted after the words in the bill "a written application for the purpose."

Mr. GREENWOOD moved to substitute "voluntary patient" for "voluntary boarder." He proposed to substitute this throughout the bill, and, by reference, in similar legislation. Colonel HENEAGE hoped that this would not alter the legal status of persons who wished to leave an institution. Mr. GREENWOOD said it would not, subject to the prescribed seventy-two hours' notice.

The amendment was approved.

Dr. VERNON DAVIES moved amendments to permit the admission of voluntary patients into single care without the special consent of the Board of Control. He was strongly in favour of the Board of Control, but not in association with the voluntary patients. In the mind of the public the Board of Control was associated with lunacy, and to bring it in would put a strong barrier in the way of early treatment among the proud working people, who were so sensitive about lunacy. The bill did not propose that early mental cases at out-patient clinics should be reported to the Board of Control. It was wrong that a poor woman who came into hospital for two or three days' rest should be notified to the Board of Control. A safeguard would, however, still be required for the infant who was sent in by guardians.

Sir BASIL PETO pointed out that at present the power of the Board of Control was only concerned with approval of institutions, and did not handle the applications of patients for treatment.

Mr. GREENWOOD said there was not the same need for scrutiny of single cases going into institutions as for those going into single care at houses of which the authorities had no official knowledge. If approval was not required in each such single case, approval would be required of the persons undertaking single care with power to revoke. If Dr. Davies withdrew his amendments, he would propose to insert "into the charge as a single patient of a person so approved, and any approval under this section may be granted subject to such conditions as the Board think proper, and may be revoked at any time." That meant the Board should approve, under conditions, the person into whose care the single patient went, but not the admission of each such patient.

Dr. DAVIES said he was willing to accept the Minister's proposition.

Discussion was then adjourned till February 27th.

Local Authorities Enabling Bill.

Municipal Trading in Milk.

Mr. MCSHANE, in the House of Commons, on February 14th, moved the second reading of the Local Authorities (Enabling) Bill. He explained that the bill was a permissive measure, placing public authorities on the same footing as limited companies if they wished to trade. In particular, he advocated municipal trading in milk. This was, he said, one of the most unsatisfactory food supplies of the people, in spite of a host of inspectors, on whom the London County Council alone spent £100,000 a year. According to the Ministry of Health, out of 67,000 samples of milk taken at random in 1928, 8.2 per cent. were adulterated. In one sample a quantity of paraldehyde was found. During the war Rotherham had a municipal supply of milk. After the war it sought powers to continue the undertaking, but these powers were refused.

Dr. SALTER seconded the motion for the second reading of the bill. He said that practically every municipal authority was breaking the law and overstepping its powers. At the present moment no borough in London could provide a subway for its citizens unless at the same time it constructed below the surface of the road a urinal. He held that local councils should have the power of manufacturing and supplying bread. Small-scale baking ought to disappear. Numbers of employees worked in overheated underground bakeries, badly ventilated and only made habitable by the constant pressure of the sanitary authorities. These dreadful little places should be scrapped, and the bread supply of great towns concentrated under municipal auspices. He himself had helped to found a modern bakery, which supplied 60,000 persons.

Dr. VERNON DAVIES asked if Dr. Salter allowed night baking.

Dr. SALTER said his bakery was obliged to carry on night baking because of the competition of small bakeries. The Factories Bill would have the effect of abolishing the practice. He went on to deal with milk, and said that 8 per cent. of the milk which came to London was definitely tuberculous. The percentage in different towns was practically never below 8 per cent., and was often as high as 20 per cent. Every year from 13,000 to 15,000 tuberculous cows were slaughtered in this country, but apparently the number of tuberculous cattle never diminished. With 2,000,000 milch cows in the country, only 850 herds were known to be tubercle-free. Every year 2,300 human beings died in this country from disease caused by the bovine bacillus, which reached them almost exclusively through tubercle-infected milk. Practically nothing was done by the Ministry of Health or the Ministry of Agriculture to protect the public from this source of infection. Mr. Somerville Hastings, Dr. Fremantle, and others, with himself, had interviewed officials of both Ministries to get some move on in this question. He was deeply disappointed to find how little progress had been made recently, and what little prospect there was of getting more done in the immediate future under the existing conditions of privately owned and privately distributed milk supply. If a town were allowed to supply milk to its inhabitants, whether by contracting with farmers and managing the delivery itself, or by obtaining the milk from its own farms, it would effect a rapid change. If surgical tuberculosis thereafter occurred every cow from which milk was drawn would have an immediate veterinary inspection, and every cow suspected of tuberculosis would be immediately eliminated. He saw no hope for the elimination of tuberculous milk except by establishment of a municipal milk supply.

Sir KINGSLEY WOOD: What about a municipal medical service?

Dr. SALTER said he strongly advocated a State medical service. The question of setting it up could only be dealt with by a national department.

Sir GERALD HURST moved the rejection of the bill.

Mr. E. D. SIMON said it was humiliating and intolerable that Manchester was not permitted to sell cheap sugar, on medical advice, to children who needed it. That had been attempted during the war, on medical advice, by the Public Health Committee, which was promptly told that it had no power to do it.

Mr. WOMERSLEY remarked that even Dr. Salter might object to being a municipalized doctor.

Dr. SALTER: Not at all; on the contrary.

Mr. GREENWOOD said his view was that the State exercised far too detailed a supervision over local authorities. Nothing would stop the grant of wider powers to local authorities in the very near future.

The bill, which applies to Scotland as well as to England and Wales, was read a second time by 150 to 124. Dr. VERNON DAVIES moved to send it to a committee of the whole House. This was defeated by 144 to 119, and the bill was sent to a Standing Committee.

Effect of Diet on the Teeth.

Asked, on February 13th, by Dr. Fremantle, if he would ensure that all children should be instructed in the effect which a diet deficient in vitamin D had upon the teeth and how decay of the teeth could be prevented by a proper choice of foodstuffs, Sir C. TREVELYAN referred to the *Handbook of Suggestions on Health Education*, issued by the Board of Education for teachers. Dr. FREMANTLE pointed out that his question referred to experiments since the Handbook was published, and asked whether the Handbook could be revised in the light of important results being issued by the Medical Research Council. Sir CHARLES TREVELYAN said he would consider the matter.

In a written answer, on the same date, Mr. GREENWOOD told Dr. Fremantle that the researches at Sheffield University, now being published by the Medical Research Council, into the effect of a proper dietary for expectant mothers and for children in the prevention of dental decay, were known to him. It was a common practice at maternity and child welfare centres to give advice as to a correct dietary, including instruction for the prevention of dental decay, and he did not consider it necessary to issue any special paper on this subject.

On February 18th Mr. JOHNSTON, replying to Dr. Fremantle, said that he had been informed of the report of recent investigations at Sheffield University, now being published by the Medical Research Council, which extended and amplified previous accounts of these important investigations into the relation of diet to the proper development of the teeth. The results did not show that oatmeal and other cereals were necessarily deleterious, but that they increased the body's requirements of vitamin D. The fact was that the Scottish people had far better teeth when they consumed more meal than they were doing to-day.

Dr. FREMANTLE: Does the hon. gentleman not realize that it is necessary to show that oatmeal by itself would be very deleterious, and that it is necessary to have such things as cod-liver oil, or something like that, with it? Mr. JOHNSTON: The same statement has been made about fish, sugar, milk, and other necessaries of life.

Mr. SANDERS: Will the hon. gentleman's department take care not to place too much importance upon the varying superstitions and illusions of the medical profession? Mr. JOHNSTON: The answer is in the affirmative.

Dr. FREMANTLE: Will the hon. gentleman deny the suggestion that the reports of the Medical Research Council under the Government are superstitions and illusions? Mr. JOHNSTON: No, Sir, but I would say they frequently contradict themselves.

Miss RATHBONE asked what proportion of the agricultural and urban workers of Scotland were in a position to pay for cod-liver oil and other articles of diet recommended. No answer was given.

Deaths from Diphtheria.

On February 12th Mr. GREENWOOD, in reply to a question by Mr. Freeman, gave the following table regarding deaths from diphtheria, for the years 1920–28.

	1920.	1921.	1922.	1923.	1924.	1925.	1926.	1927.	1928.
England (excluding Monmouthshire)	5,150	4,353	3,783	2,420	2,299	2,544	2,177	2,535	2,929
Wales and Monmouthshire	516	419	295	242	202	230	217	197	262
Scotland	699	611	536	492	442	505	490	485	488
Canada	Not available	1,297	1,024	851	848	615	546	1,012	913
United States of America	13,395	15,520	13,104	11,014	8,726	7,403	7,114	8,425	8,233
Germany	7,891	5,953	4,490	4,413	3,624	2,799	2,189	2,512	Not available

Silicosis.

On February 13th Mr. CLYNES said, in reply to Mr. Hoffman, that the central bureau for the purposes of the diagnosis and treatment of silicosis, for research purposes and training, would be in Sheffield. He could not say when the proposed Silicosis Bill would be introduced, but everything would be done to expedite the matter.

On February 20th, replying to Mr. Maridy Jones, Mr. Clynes said that, though he appreciated the hardship in cases of silicosis prior to January 1st, 1929, he had no power under the Act to give the Various Industries (Silicosis) Scheme any retrospective application. No figures were available as to the number of miners granted compensation under the scheme for the year 1929, as the returns were not due till March 1st, and as tabulation of cases for each coalfield occupied considerable time, it would be some months before he could furnish reliable figures for 1929.

On February 20th, Mr. Clynes told Mr. Hopkin that he still had no evidence to show that the condition of the lungs described as anthracosis was a cause of disablement. The Medical Research Council were setting up an expert committee to institute and co-ordinate research into pulmonary disease from silica and other dusts. With the concurrence of the Mines Department Mr. Clynes proposed to bring the question of the effects of coal dust under the committee's consideration.

National Health Insurance.

In reply to Mr. Rhys Davies, on February 12th, Mr. GREENWOOD said it was estimated that during the five years 1924–28 the number of new entrants to health insurance averaged rather over 1,000,000 a year, divided almost equally between men and women, the figures in 1926 being somewhat higher than the average owing to a special accession of voluntary contributors under the Contributory Pensions Act, 1925. No information was available regarding the number of persons joining approved societies.

Replying to Mr. Sorensen, on February 20th, Mr. GREENWOOD said insurance doctors were not only entitled, but required by their terms of service, to order on the proper form any drugs or prescribed appliances reasonably necessary for treatment of their patients. Dr. VERNON DAVIES asked whether it was not a fact that doctors were not allowed to prescribe medicine for panel patients regardless of cost. Mr. GREENWOOD answered that the law required them to prescribe what was reasonable for the cases.

Psittacosis.—Mr. GREENWOOD told Sir George Bowyer, on February 13th, that the question of placing an embargo on parrots, with a view to the danger of a spread of parrot disease, was under consideration, though at present he was not satisfied that such a measure was necessary. He had seen a newspaper report of the inquest on Miss Rogers, who succumbed to this disease. The steps taken by his department had been summarized in a memorandum recently issued to local authorities and now on sale. In reply to Mr. Hacking, on February 20th, Mr. Greenwood said that the parrots associated with cases of psittacosis in this country were mostly green parrots imported from South America. He could give no definite assurance that parrots which had been in the country a certain time and had not been in contact with the disease were immune from spreading infection, but the risk was negligible.

Tubercle Bacilli in Milk.—Mr. GREENWOOD, replying on February 17th to Mr. Lawther, said that he understood that some samples of milk alleged to have been pasteurized had been found by local authorities to contain tubercle bacilli. Pasteurized and tuberculin-tested (Grade A) milks were not examined for the tubercle bacillus as a matter of routine, and he could not say how many samples had been so examined. He had reports of a few instances in which tubercle bacilli had been found in the milks. He was not aware of any examinations which had shown the presence of bovine tubercle bacilli in children brought up entirely on pasteurized milk.

Deaths from Tuberculosis.—On February 17th, in reply to Mr. Bromley, Mr. GREENWOOD said that the number of deaths certified as due to tuberculosis in England and Wales in 1927 and 1928 were 33,173 and 36,023 respectively. The figures for 1929 were not yet available.

Refuse Dumps.—Replying to Dr. Fremantle, on February 18th, Mr. W. R. SMITH said he understood that representations of the danger to shipping caused by smoke from the South Hornchurch dumps had been made by the Port of London Authority to the Departmental Committee which was considering the question of the collection and disposal of London refuse.

Women's Medical Service in India.—Mr. BENN, replying to Major Pole, on February 24th, said that an annual grant of Rs.3,70,000 was made by the Government of India to the National Association for Supplying Medical Aid to the Women of India, towards the cost of the women's medical service. The grant was administered by the council of the association.

Storage of Fresh Fish.—Replying to questions by Mr. A. M. Samuel, on February 24th, about the steps taken to ensure the freshness of the fish supply, Mr. BUXTON said the provision of galvanized iron storage shelves with waste water gutters formed part of the recommendations of the report on the handling and storage of white fish at sea, recently issued by the Department of Scientific and Industrial Research. Steps were already being taken by some owners to equip their vessels with the apparatus necessary for carrying out the recommendations in the report. Adequate safeguards against the exposure for sale of fish intended for the food of man, but unfit for human consumption, already existed in Public Health Acts, under which such fish might be condemned and the owner or person in possession fined or imprisoned. The description "stale" applied to fish was a trade term, and did not imply that it was unfit for consumption. He combated the suggestion that fish curers made a practice of buying unwholesome fish.

Flogging in Prisons.—Mr. CLYNES, replying to Mr. Hastings on February 17th, said in no case within the memory of present officers of the prison service had the administration of corporal punishment taken place in two or more stages. If the medical officer stopped a flogging on medical grounds that was final, and the flogging was never resumed at a later date. Earlier in the week, in reply to a question, Mr. Clynes said that girls in reformatories were never flogged, as such treatment would be contrary to the rules and spirit of reformatory schools, Borstal institutions, or prisons. In girls' schools caning on the hands with a light cane was allowed, but only one case occurred last year.

Drunkenness: Doctors' Reports.—Replying, on February 13th, to Sir N. Grattan-Doyle, who asked whether any action was to be taken concerning the observations of metropolitan magistrates respecting the recent Order that the doctor's report as to the condition of a person charged with drunkenness should not be presented by the police officers in the witness-box, Mr. CLYNES stated that this Order was not to the effect stated. It did away with the practice of including, in a memorandum of expenses incurred by the police, the short effect of any medical report for which expense had been incurred, and with the practice of referring to this memorandum in court, in certain circumstances, without evidence on the point being taken. He had seen or received representations from individual magistrates which would be carefully considered. Should any further action appear necessary or desirable it would be taken.

Death from Anthrax.—Replying to Mr. Jowett, on February 13th, Mr. CLYNES said he had received a report on the death from anthrax of a woman wool-sorter in Bradford. Mr. Clynes said the evidence of Dr. Eurich, the bacteriologist, showed that this woman had been sorting Syrian grey wool, but previous to the onset of the disease she had also sorted other material, and the precise origin of infection did not seem to have been established at the inquest. The extension of the wool-sorting regulations deserved, and would receive, prompt and serious attention, but before any decision was reached it would be necessary to make further inquiries and review all the information available. Mr. Clynes added that the factory inspector reported that the regulations were fully observed by the firm in question, and were applied not only to scheduled, but also to non-scheduled wools, so that even if grey Syrian had been scheduled it would not apparently have made any difference in this case.

Dangerous Drugs.—On February 19th Mr. A. HENDERSON told Colonel Heneage that British representatives in Turkey had from time to time impressed upon the Turkish Government the desirability of their acceding to the Opium Conventions, and that the attitude of Persia had been the subject of discussion at the League of Nations, of which Persia was a member. Neither the Turkish nor the Persian Government could be in any doubt of the importance attached by the British Government, as by other parties to the Opium Conventions, to their undertaking at an early date the obligations of these instruments. On February 24th Mr. SHORT, in reply to Dr. Fremantle, said that the Home Office had for a long time done everything in its power to promote co-operation in the enforcement of the international conventions relating to dangerous drugs and in the suppression of the illicit traffic. The League of Nations Advisory Committee, on which the British Government was represented, had given constant attention to this question. As a result of the recommendations which they had drawn up, great progress in co-ordinated action had been made. The discoveries recently brought before the Advisory Committee on Opium were, in fact, made as a result of co-operation between the authorities of several countries. He understood that the Advisory Committee, in its report to the Council of the League on the proceedings at its recent meeting, made further recommendations on the subject. These would receive the careful and sympathetic consideration of the British Government.

Medical Inspectors of Factories.—Answering Dr. Vernon Davies on February 19th, Mr. CLYNES said medical inspectors of factories were appointed in pursuance of the general powers conferred by Section 118 of the Factory and Workshop Act, 1901, for the appointment of such inspectors as might be necessary for the execution of the Act. They constituted a separate, but integral, branch of the Factory Department. The senior medical inspector who was in charge of the branch acted under the directions of the chief inspector of factories. He could not accept Dr. Davies's suggestion that, in view of the recommendation adopted by the country at the Washington Conference, he should constitute a separate health department for this service. Mr. Clynes said the intention of the Washington recommendation was to secure the establishment of a medical branch in connexion with factory inspection, and this was effected in the existing arrangements.

Propagation of Mentally Deficient.—Major GLYN asked, on February 19th, whether Mr. Clynes's attention had been drawn to public statements by judges regarding the consequences of mentally deficient persons bearing children, and whether he would set up a committee to inquire into the whole matter, unless this subject could forthwith be referred to an existing commission, and legislation in accordance with their recommendations be introduced at an early date. Mr. GREENWOOD replied that the statements in question had for some time past been under consideration. The issues involved were far-reaching and controversial. They could only be examined effectively by a suitable body specially set up for the purpose, and such an investigation could not at present be undertaken.

News in Brief.

From the reports of the Government chemist on the samples of imported preserved milk analysed by his department, Mr. Greenwood is satisfied that all the milks examined were nutritious, and that they did not contain anything to render them harmful as an article of diet.

The total number of persons killed below ground in mines in the United Kingdom during 1929 was 994, of whom 403 were at the working face, 176 on roads, 220 in haulage accidents, 34 concerned in explosions of firedamp or coal dust, and 161 in other underground accidents.

During 1929 451 experiments (all inoculations), of which 74 were on dogs, were performed with the object of discovering a prophylactic serum for distemper.

Expenditure by local authorities in England and Wales during the year ended March 31st, 1928, on the administration of the Vaccination Acts amounted to £190,754. The cost of the Government lymph establishment, after allowing for receipts from the sale of lymph, was £13,030.

The Minister of Agriculture is convinced, after inquiry, that the embargo on Continental pork is necessary.

In England and Wales, on January 4th, 1930, those receiving institutional relief numbered 222,124, and those receiving domiciliary relief 871,220. The total of 1,093,344 excludes lunatics in county and borough asylums, casuals, and persons in receipt of domiciliary medical relief only.

The memorandum explaining the effect of the Local Government Act, 1929, upon the provisions of the Lunacy Acts will be issued as long as possible in advance of the appointed day on which the relevant parts of the Act come into operation.

Medical News.

PROFESSOR G. ELLIOT SMITH, M.D., F.R.S., will give a lecture on "The Human Brain" at the house of the Royal Society of Arts, John Street, Adelphi, W.C., on Wednesday, March 12th, at 8 p.m. The chair will be taken by Sir Oliver Lodge.

THE Institute of Ray Therapy in Camden Road, St. Pancras, of which an account was given in the *Journal* of January 25th (p. 163), will be formally opened by the Lord Mayor of London on Thursday, March 13th, at 3 o'clock.

A CHADWICK Trust lecture on infant welfare schemes will be given by Dr. Stella Churchill at the house of the Medical Society of London, 11, Chandos Street, W.1, on Monday, March 3rd. The chair will be taken by Sir William J. Collins at 5.15 p.m.

AT a meeting of the Royal Sanitary Institute to be held on March 14th, in the Council Chamber, Middlesbrough, a discussion on "Ventilation of cinemas, etc.," will be opened by Dr. W. S. Walton. The chair will be taken at 4 p.m. by Dr. Charles Porter.

AN announcement by the Royal Society regarding the Smithson Research Fellowship appears in our advertisement pages. Applications are invited from British subjects for this Fellowship, established for research in natural science with a view to the discovery of new laws and principles. Preference will be given to candidates not more than 35 years of age, and ordinarily the Fellow will be required to carry out his investigation in the University of Cambridge.

A POST-GRADUATE course in tuberculosis, arranged by the Joint Tuberculosis Council, will be held in the X-ray Department of the Hospital for Consumption and Diseases of the Chest, Brompton, S.W.3, from March 17th to 22nd. The course will be conducted by Dr. Stanley Melville, assisted by members of the hospital staff. At the first meeting, at 2 p.m., arrangements will be made for dividing the class, which is limited to twenty-five members, into small groups for studies in the *x*-ray department (screening and dark room, reporting, diagnosis) and for visiting the wards and out-patient department. The provisional programme includes lectures on the diagnosis (*x*-ray) and on the surgical aspect of pulmonary tuberculosis, technique, bronchiectasis and lung abscess, intrathoracic new growths, and dental radiology. Clinical demonstrations will be given during the week, and, if possible, demonstrations of the technique of lipiodol injection. There will also be opportunities for visiting manufacturers, and for the discussion of any films that members of the class bring with them. The fee for the course is three guineas.

THE Fellowship of Medicine announces that Professor F. R. Fraser will lecture on the uses and abuses of digitalis at the Medical Society Lecture Room at 11, Chandos Street, Cavendish Square, on Tuesday, March 4th, at 4 p.m. Mr. Nicol Rankin will give a special demonstration on the guillotine enucleation of tonsils in children at the Central London Throat, Nose, and Ear Hospital, Gray's Inn Road, on Tuesday, March 4th, at 9 a.m. A demonstration on clinical laboratory findings will be given by Dr. F. A. Knott at the Royal Waterloo Hospital on Thursday, March 6th, at 2.30 p.m. The lecture and demonstrations are free to medical practitioners. Special courses on the following subjects will be given in March: diseases of the chest at the Brompton Hospital from March 10th to 15th, occupying all day; orthopaedics at the Royal National Orthopaedic Hospital from March 10th to 22nd, occupying all day; neurology at the West End Hospital for Nervous Diseases from March 17th to April 12th, every afternoon at 5 o'clock; venereal diseases at the London Lock Hospital from March 17th to April 12th, during the afternoons and evenings; medicine, surgery, and gynaecology at the Royal Waterloo Hospital from March 24th to April 12th, in the afternoons and some mornings; and gastro-enterology at the Prince of Wales's Hospital from March 31st to April 5th, occupying all the day. Copies of all syllabuses will be sent on application to the Secretary, Fellowship of Medicine.

THE post-graduate lectures and demonstrations on medical, surgical, and special subjects given by the honorary staff of the Manchester Royal Infirmary will be resumed on Tuesday, March 4th, and will be continued each week, with the exception of April 22nd, till June 3rd. On Fridays, commencing March 7th, demonstrations of clinical cases and methods will be given in the wards and special departments; they will be continued (with the exceptions of April 18th and 25th) until May 30th. The lectures and demonstrations, for which there is no fee, will commence at 4.15 p.m., and tea will be served at 3.45 p.m.

SOME 350 medical men and women and their guests were present at the dinner of the London Irish Medical Golfing Society, which was held at the May Fair Hotel on February 20th, with the president, Mr. Hugh Lett, in the chair. All the Services were represented by medical men, and among the distinguished guests were Lord Moynihan of Leeds, Lord Russell of Killowen, Mr. Arthur Greenwood, Minister of Health, Mr. A. V. Alexander, First Lord of the Admiralty, and Sir Robert Stanton Woods. In the course of the evening Lord Russell of Killowen, Mr. Hugh Lett, Mr. Michael Smith, and Lord Moynihan made brilliant speeches in proposing and replying to toasts.

THE second number of the new series of the *Liverpool Medico-Chirurgical Journal* has now appeared. It contains the full text of the Sir William Mitchell Banks Memorial Lecture, which was delivered in November, 1929, at the University of Liverpool by Professor Claude Regaud, who took for his subject "Radium therapy in the treatment of malignant tumours." There is also a pen portrait of the late Professor Ernest Glynn, and various clinical articles, as well as reviews. This journal is published half-yearly by Messrs. H. K. Lewis and Co., Ltd., 136, Gower Street, W.C.1. The price for the present issue—which is a double one—is 5s.

THE date of the forthcoming congress of the International Society for Microbiology, given in our last issue as June 25th, has been altered by the Central Committee in Paris to July 20th to 25th. To facilitate travelling arrangements, those intending to be present at the congress are invited to communicate with Professor W. W. C. Topley, London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1, or Dr. R. T. St. John-Brooks, Lister Institute of Preventive Medicine, Chelsea Gardens, S.W.3.

THE twenty-sixth Italian congress of dermo-syphilography will be held at Rome from April 24th to 26th. Further information can be obtained from the secretary, Dr. Vincenzo Montesano, Piazza Campo Marzio 3, Roma 120.

THE Gas Light and Coke Company, the oldest and largest gas company in the world, has issued a booklet on the occasion of its absorption of the areas of the Grays and Tilbury Gas Company and the Pinner Gas Company, Ltd. It is now authorized to supply gas over an area of 460 square miles. In 1929 it served a population of over four million, and employed twenty thousand people. In spite of the competition of the electrical industry, the increase in the annual sale of gas by the company during the last five years is only about eleven million therms less than the increase in the whole of the preceding twenty. It appears that the highest consumption of gas per acre in any residential district is in the Harley Street area, and that about five thousand members of the medical profession are "personal users" of gas fires. The booklet is illustrated, and particulars are given of research, training, and testing departments. There are also sections on the making of gas, central heating, and the application of gas in industry.

THE Joint Tuberculosis Council has prepared and circulated to all medical officers of health and tuberculosis officers a memorandum on the notification of tuberculosis with special reference to the chief objectives of this procedure, the clinical indications for it, and the ways in which medical practitioners can assist in preventing tuberculosis. Notification is urged (1) when suggestive constitutional symptoms are present with corroborative evidence; (2) when tubercle bacilli have been found; (3) in cases of haemoptysis or pleural effusion where there are other suggestive symptoms or signs; (4) in acute general tuberculosis and tuberculous meningitis; (5) in persistent chronic adenitis, arthritis, or bone disease where other causes than tuberculosis have been excluded; (6) in tuberculous dermatitis and lupus vulgaris; and (7) in *tuberculosis of the abdomen, the genito-urinary tract*, or elsewhere.

A STATE Institute of Hygiene has been brought into being in Prague, and in connexion with it a quarterly journal, entitled *Les Travaux de l'Institute d'Hygiene Publique de l'Etat Tchécoslovaque*, is to be published. The first issue, dated January, 1930, contains an account of the organization of this institute and an illustrated description of the section concerned with serums and bacterial vaccines. Further information may be obtained from the secretary of the editorial committee, Korunní Tr., Prague XII, Czechoslovakia.

A COMPLETE course of French study at the Sorbonne, Paris, is announced for June 29th to August 20th. The course consists of three parts: (1) preparatory work, with afternoon visits in Paris; (2) afternoon lectures (more advanced) on present-day questions in literature, politics, and economics; (3) eight days' journey, in small groups, in Western France. A second course, July 28th to August 24th, will only comprise the parts (1) and (2). All arrangements are under the direction of M. Henri Goy, Directeur du Bureau des Renseignements Scientifiques, Sorbonne, Paris, to whom inquiries should be addressed.

THE eighth international congress of the history of medicine will be held at Rome under the presidency of Professor Pietro Capparoni from September 22nd to the 27th.

THE sixth international congress of industrial medicine will be held at Geneva in August, 1931, when the following subjects will be discussed: (1) The remote results and evolution of traumatic lesions of the spinal column. (2) Injuries to blood vessels (arteritis and thrombo-phlebitis). (3) Cutaneous infections in relation to industrial accidents. (4) Previous condition in relation to consequences of industrial accidents. Further information can be obtained from the general secretary, Dr. Yersin, 1, Rue du Rhone, Geneva.

THE KING has approved of the appointment of Dr. Norman Lockhart Joynt, *M.C.*, to be an official member of the Executive Council of the Presidency of the Virgin Islands.

DR. ROBERT DOERR, professor of hygiene at Basle, has been awarded the Josef Schneider gold medal by the University of Würzburg.

DR. J. TRICOT-ROYER of Antwerp, president of the International Society of the History of Medicine, has been made an Officer of the Crown of Italy.

THE fortieth anniversary of the École de Psychologie of Paris, founded by Dr. Bérillon, has been celebrated at a meeting attended by Professors Richet, Pierre Janet, Roux, Menetrier, and Marcel Labbé.

THE following appointments have recently been made in *foreign faculties of medicine*: Dr. *Ernst Leupold*, professor of general pathology and pathological anatomy at Cologne; Dr. H. Burckhardt of Marburg, professor of medicine at Kiew in the Ukraine; Professor Poffe, dean of the medical faculty at Rostock; and Dr. Louis Debayle, dean of the medical faculty at Nicaragua.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9861, 9862, 9863*, and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medocera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 21361 Edinburgh).

QUERIES AND ANSWERS.

PAIN FOLLOWING HERPES ZOSTER.

DR. NORMAN WILSON (Alassio) writes: I should be grateful for suggestions for the treatment of persistent pain following herpes zoster.

TREATMENT OF HAEMORRHOIDS.

DR. G. FRANCIS SMITH (Watford) writes: I should be glad to know what is regarded as the best treatment for haemorrhoids, particularly with regard to injections. Removal is unpopular, and my experience of urethane and quinine, for instance, is unsatisfactory. Carbolic seems occasionally to cause sloughing.

DIARRHOEA FOLLOWING INTAKE OF SUGAR.

"R. M. R." writes: I should like to have an opinion on the following case. The mother of a boy, aged 4, reports "whenever he takes anything sweet, whether sugar, confectionery, or fruit, it runs through him." He has four actions of the bowels during the day; the motions are generally fluid, and of a dark colour. He has had this trouble for two months. He looks well and is very active. There used to be pain when the bowels acted, but not now. He has lost flesh. He improved on reducing the sugar and prescribing dilute hydrochloric acid, but the trouble does not clear up.

LEAD URINALYSIS.

"M. D." writes: I wonder if Dr. W. E. Cooke of Wigan (February 22nd, p. 359) was able to detect lead in the urine of his cases of plumbism. Lately in a marked case, in a house painter, of lead colic with the blue line in the gums I failed to detect lead in the urine by the test given in Taylor's *Medicine*; in this test a little ammonium oxalate is added to the urine, and there is a deposit of lead on a strip of magnesium immersed in it. This may be verified by treatment with iodine fumes causing the yellow iodide to appear. Can any of your readers say if the test given in Taylor's *Medicine* is trustworthy?

BROKEN SLEEP.

"M. W." (London), replying to the question of "Broken Sleep" in the *Journal* of February 22nd (p. 371), writes: I suggest that "D. S." should try dial 1½ grains at bedtime if the insomnia is not associated with pain.

"B. H." writes: "D. S.'s" trouble may be in part due to chilliness at 3 or 4 a.m., or possibly to early morning noises, after which he wakens. Some form of head covering and a screen round the head of the bed might be useful, and medinal 7½ grains at bedtime occasionally is very effective.

"F. A. B." writes: Sleeplessness coming on about 3 to 4 o'clock every morning suggests an acid dyspepsia. "D. S." might try Parke Davis's antacid lozenge.

TURBINATE CAUTERIZATION FOR COLDS.

"RELIEVED" writes: Having derived considerable benefit in the form of freedom from colds by having my turbinates cauterized, I repeated the procedure two years later, purely as a prophylactic measure. I should be grateful for opinions as to how often it might be advisable to be recauterized, from this point of view.

PRECIPITATE EJACULATION.

"R. M. L." (Birmingham) writes in reply to "N. D." (February 15th, p. 320): *Ejaculatio praecox* is a psychological mechanism, and is usually due to an unconscious fear of lack of virility. Appropriate psychological treatment will effect a cure.

URTICARIA FOLLOWING SERUM ADMINISTRATION.

DR. E. W. GOODALL (Hemingford Abbots, Hunts) writes in reply to "C. E.'s" questions in the *Journal* of February 22nd: The patient is probably asthmatically sensitive to horse emanations and products, and the urticaria was due to the horse serum. An asthmatic subject should not be given antidiphtheria serum in the event of an attack of diphtheria without a preliminary skin test, to ascertain whether he is susceptible or not. If he is susceptible, the serum should not be given, even in small doses.

INCOME TAX.

Change in Proprietorship; Cash Basis.

"W. R. B." was in partnership with A. until September, 1928; A. then retired, and "W. R. B." took an assistant. The practice has been assessed on the cash basis for many years. "W. R. B." did not purchase A.'s share of the debts outstanding at his retirement, and the revenue authorities are now claiming tax from A. on sums paid over to him in respect of such debts. Due notice was given requiring the authorities to assess the practice from September, 1928, as if it had then ceased and been restarted. Is this correct?

*** No; we can find no justification in the Income Tax Acts for assessing A. for a period subsequent to his retirement from the practice. On the other hand, "W. R. B." will be assessable in respect of the full profits of the practice, and if only that portion of the cash receipts which is retained by him is included in his income tax return, that statement will not represent the full gross income of the practice. Consequently, the alternatives are (1) to allow the existing assessments to remain unchallenged; (2) to claim a discharge of the assessments on A., and (*a*) for "W. R. B.'s" liability to be computed on the basis of including all post-October 1st, 1928, receipts as his, or (*b*) to render the returns for the financial years 1929–30 onwards on the basis of the value of the bookings, and not on the cash receipts.

Public Appointment; Motor Expenses.

P. H." is an assistant county medical officer, and his council makes him an allowance for travelling expenses calculated at 4½d. per mile. Can he claim "any deduction from income tax, and, if so, at what rate?"

*** The income tax allowance is restricted to expenses incurred wholly, exclusively, and necessarily in the performance of the duties of the office. We are of opinion that "P. H." can clearly claim a deduction of the excess of expenses so calculated over the amount of the allowance based on the mileage rate. But the authorities will no doubt start from the assumption that the council's allowance is adequate, and strict proof of the amount of the excess will be required—for instance, if "P. H." uses a four-seater car when, for official purposes, a two-seater car would serve the purpose, some reduction in his actual expenditure would strictly be justified in calculating the allowance.

LETTERS, NOTES, ETC.

A GENERAL METHOD FOR MALLORY'S TRIPLE STAIN.

MISS E. E. HEWER, D.Sc., lecturer in histology at the London School of Medicine for Women, writes: In the *Journal* of February 15th (p. 282) Dr. MacConaill outlines a general method for Mallory's triple stain, again emphasizing the fact that the material need not be fixed in a sublimate mixture. In a paper published in June, 1926, in the *Journal of the Royal Microscopical Society*, and entitled "The effect of fixative on staining reaction," I drew attention to the fact that Mallory's triple stain can be used after such fixatives as formol, formol saline, formol-acetic-Muller, Bouin, and neutral formol-Muller, with only slight variations in the colour reactions obtained. In view of the fact that this staining method is of such value, it is most regrettable that textbooks still continue to copy the statement as to Zenker fixation, in spite of the well-known excellent results of using other fixatives.

LARGE HYDROCELES.

DR. ROBERT B. COLEMAN (Bromley, Kent) writes: On September 7th, 1916, at the C.M.S. Hospital, Old Cairo, I operated on an Egyptian patient for hydrocele, the fluid from which measured 27 pints (540 oz., against 192 oz. reported). This hydrocele was of the bilocular variety—a single sac, but hour-glass in shape—the upper part being behind the peritoneum in the abdomen. The patient made an excellent recovery, and since the testicle had to be removed with it, owing to the very elongated cord, the sac was later inflated and allowed to dry; it remains an interesting specimen to this day. The case was reported in the *British Medical Journal* of December 7th, 1918 (p. 629).

AXILLARY BREAST.

DR. R. Y. STONES (Neston, Wirral) writes: In the *Journal* of February 15th (p. 283) Dr. R. E. Anderson describes two cases of axillary breast, and details of the following case, which misled me, may be of interest to others. An African woman, about 25 years old, a few months pregnant, was admitted on Christmas Eve, 1922, to my hospital at Maseno, Kenya Colony. Her temperature rose rapidly. As there were always sporadic cases of plague about, though no epidemic was occurring at the time, I carefully examined her for buboes. She complained of pain in the right axilla, and on examination a firm, tender swelling, about the size of a walnut, was found. I aspirated this swelling, and, to my surprise, drew off colostrum. The patient died later in the night, and a further examination of her axilla revealed the galactocele, with a small commencing bubo alongside, which I had missed. Aspiration of this second swelling after death proved the presence of *B. pestis*.

RHYTHMIC HAIR MOVEMENT.

DR. J. C. BENNETT (Hyde, Cheshire) writes: I should like to record a strange case of rhythmic hair movement which I observed in a patient suffering from scirrhous cancer of the breast that had been treated by implanted radium tubes. The patient, aged 32, had a small hard nodule in the left breast, with slight implication of the skin. On admission to hospital she was found to have small but definite glands in the axilla and in the supraclavicular fossa, and a number of tubes containing radium were inserted at and around the tumour. Reaction was very great, and superficial sloughing of the skin occurred. When this had healed a small hard mass still persisted in the upper and inner breast segment. Sixteen more tubes were then buried in the tissues, and shortly after, when the patient left hospital, she again came to see me. There was great pain and some swelling in the left arm, and a similar condition in the breast and around the tendons of the pectoral muscles. Whilst examining this I discovered what struck me as a rather curious phenomenon. The small fine hairs in the region of the outer side of the infraclavicular fossa and supraclavicular fossa were exhibiting a rhythmic rise and fall at intervals of about five seconds. The skin would show the characteristic "gooseflesh" condition and then smooth out again as one watched it—the hairs standing erect and then subsiding. Evidently waves of nervous impulse were being thrown into the sympathetic motor supply of the arrectores pilorum. I do not know the significance of this, but it was evidently caused by the action of radium on the local sympathetic nerves. As the other side of the chest was not affected, it would appear to bear out Langley's conclusions that there is no true reflex arc, as there is in the medullated nerves, and that the effect was produced by local means. Whatever the cause, it was a rather interesting and, to me, strange occurrence.

PRESCRIBING OF ASPIRIN.

AT a meeting of the Pharmaceutical Society, held in Edinburgh, on February 19th, Mr. D. B. Dott read a paper on acetylsalicylic acid in solution with potassium citrate. The questions dealt with were whether aspirin was dissolved in water by means of sodium bicarbonate retained character and therapeutic properties method of dissolving aspirin with any advantage. He stated that aspirin remained almost entirely stable under either condition, and that either solution gave a satisfactory method of administering this drug.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 49, 50, 51, 52, 53, 56, 57, 58, and 59 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 54 and 55.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 67.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

203. Anatoxin Prophylaxis against Diphtheria.

S. AHRENDT LARSEN (*Ugeskrift for Laeger*, December 19th, 1929, p. 1154), of the epidemiological division of the State Serum Institute in Copenhagen, states that this institute has, during the last few years, inoculated more than 2,500 children with anatoxin, which, in Denmark, is preferred to the toxin-antitoxin system of preventive inoculation, because the former is not poisonous and can be kept at room temperature for an unlimited period without deteriorating. Further, the fact that anatoxin contains no serum, and cannot, therefore, provoke serum disease, is a point in its favour when it is compared with the toxin-antitoxin mixture. The ability of anatoxin to convert a Schick-positive to a Schick-negative reaction was demonstrated in a group of 40 children, all of whom were Schick-positive at the beginning, and 36 of whom were Schick-negative two months after the first injection. The injections of anatoxin being voluntary, there was a certain number of children who were able to serve as controls because of objections raised by their parents to this procedure. In one children's home, exposed to infection with diphtheria, there were 40 children inoculated, of whom not a single one developed diphtheria, whereas among the 16 children who were not inoculated there were 6 who developed the disease. In the same home, between three and four months later, a new epidemic of diphtheria broke out, and all of the 5 new cases of diphtheria occurred among the 32 children who had not been inoculated, none of the 21 inoculated children developing this disease. All the injections of anatoxin were given subcutaneously, great care being taken not to introduce it into the muscles. The first injection of 0.5 c.cm. was followed about two weeks later by an injection of 1 c.cm.; the third and last injection 1 (c.cm.) was given after a week. The author recommends, however, an interval of at least three weeks between the first and second injections. The Schick test was not performed beforehand as it is already known that about 80 per cent. of children between the ages of 1 and 7 years are Schick-positive, and a fourth injection in each case seemed undesirable. The author has himself seen no case of anaphylactic shock after the second injection, but he has been informed by a Danish colleague of a case in which artificial respiration was required after the second injection. The child suffered, however, no permanent ill effects.

204. The Basal Metabolism in Heart Disease.

O. JERVELL (*Norsk Mag. f. Laegevid.*, December, 1929, p. 1269) has investigated the basal metabolism in 45 patients suffering from different forms of cardiac disease; in 14 cases it was found to be somewhat below the normal, in 22 it was raised 10 per cent. or more, in 17 more than 15 per cent., and in 4 over 50 per cent. Four out of 16 cases of mitral disease, and 4 out of 6 cases of aortic insufficiency, showed an increased basal metabolism; 12 cases with hypertension gave decidedly high values, even in the presence of compensation. No parallelism was found to exist between a rise of blood pressure and increased metabolism. Cases of hypertension, however, were more frequently accompanied by increased basal metabolism than were cases with normal or only slightly raised blood pressure. Compensated cases without rise of blood pressure, as well as 5 cases of neurotic heart, all showed a normal basal metabolism. Increased basal metabolism in patients with heart disease is of great diagnostic importance when Graves's disease may possibly be present; in such circumstances it may be supposed that the increase may sometimes be due in part to cardiac insufficiency or hypertension, and not only to thyroid intoxication as such. The increased consumption of oxygen is probably due to a defective resynthesis of lactic acid into glycose, as shown by Eppinger and his collaborators.

205. The Association of Pulmonary Gangrene and Tuberculosis.

M. ROCH and G. BICKEL (*Rev. Méd. de la Suisse Romande*, January 25th, 1930, p. 25) remark that little is known about the etiology of pulmonary gangrene, and particularly about the local parenchymatous changes which predispose to that infection. While the healthy pulmonary parenchyma is frequently invaded by certain aerobes, such as the pneumococcus and tubercle bacillus, it offers a much greater resistance to the anaerobes of gangrene. This explains both the rarity of forms of spontaneous infection and the fact that the infection, when it does occur, is found almost exclusively in lungs which have been previously impaired. The most important predisposing cause of pulmonary gangrene is bronchial dilatation, and little importance has been attached to the part taken by tuberculosis in the genesis of the disease. Most writers insist on the antagonism existing between the tubercle bacillus and the putrefactive anaerobes, and agree with von Leyden that the coexistence of tuberculosis and pulmonary gangrene is very exceptional. The present authors do not consider that this association, though infrequent, is so rare as is usually considered, and cite cases in support of this assertion. They arrange such cases in four groups: those in which the pathogenesis of the gangrene is quite separate from that of the tuberculosis, and the association of the two is a mere coincidence; those in which the gangrene is the result of an extension to the lung parenchyma of an infection following bronchial dilatation, or of a fetid bronchitis accompanying the tuberculosis; those in which the gangrene develops in a tuberculous area; and those in which gangrene constitutes the primary lesion, tuberculosis developing much later. Cases are reported illustrating each group. The authors maintain, however, that an antagonism does exist in some respects between the two diseases, and that, in general, gangrene only appears when the tuberculosis is latent. This, they add, is somewhat astonishing, as it would be thought that a debilitating disease, such as tuberculosis, would diminish the patient's powers of resistance to all other infections.

206. Etiology of Post-vaccinal Eruptions.

P. SEIER (*Derm. Woch.*, October 19th, 1929, p. 1511) states that a post-vaccinal exanthem, an eruption occurring eight to twelve days after vaccination, though known to Jenner, is an exceptional occurrence. As a rule it does not cause any constitutional disturbance. It may or may not be accompanied by a rise of temperature, and usually disappears in a few days without leaving a trace or at most causing only slight pigmentation. The exanthem may be morbilliform, scarlatiniform, urticarial, or papular. The rarest variety, of which the author records a case with an account of a biopsy, in a male infant, aged 1 year, is that resembling erythema multiforme. Two different views are held as to the nature of post-vaccinal eruptions. While Kalischer, Sobotka, Fürst, Huguenin, Rille, Groth, and Pirquet regard them as specific, like generalized vaccinia, others, including Bohn, Behrend, Schimmelpfenig, Pfeiffer, Epstein, Jochmann, and De Biehler, do not consider them specific, but analogous to toxin, drug, or anaphylactic rashes, and possibly attributable to absorption of the contents of the pustules. Although the author was unable to inoculate vaccinia on the cornea of a rabbit with the contents of a vesicle, he succeeded in finding changes in one of the vesicles resembling Guarnieri's corpuscles. He therefore concludes that his case was an example of generalization of the virus of vaccinia.

Surgery.

207. Traumatic Rupture of the Innominate Artery.

J. FEUZ (*Zentralbl. f. Chir.*, December 21st, 1929, p. 3203) records a case which is of interest owing to its rarity and the difficulties of diagnosis. A man, aged 27, while driving a motor car, ran it into a telegraph pole in order to avoid a car coming in the opposite direction. His chest was driven violently against the steering wheel, and he was admitted to hospital shortly afterwards in a condition of shock. There was considerable cyanosis of the face; the respiration was superficial and laboured, and there was blood-stained expectoration. The right radial pulse could not be felt, while the left was soft and rapid. A few ecchymoses were seen over the sternum, and there was tenderness of the whole of the right half of the thorax. Death ensued a few hours after admission. At the necropsy about 300 c.cm. of fluid blood was found in the right pleural cavity, and about 100 c.cm. in the left; the pleura was sprinkled over with small haemorrhages. The lungs were emphysematous, and showed many haemorrhagic foci. The myocardium was intact, but there were numerous small haemorrhages in the endocardium. The innominate artery was ruptured about 1.5 cm. from its origin, and the ruptured surface was surrounded by greyish irregular clots; the neighbouring tissue was soaked with clotted blood. No signs of syphilis or arterio-sclerosis were found in the artery, nor were any pathological changes found in the vascular system. With the exception of the

right second rib, which was fractured, no bony injuries had occurred. The absence of any damage to the sternum, clavicle, or first rib excluded the possibility of the artery having been directly injured by a fragment of bone. The rupture must have been due either to a sudden violent compression or to a violent rise of intravascular pressure at a point where the suddenly compressed artery was more or less completely occluded.

208. Liposarcoma of Mammary Gland.

R. A. LIFVENDAHL (*Surg., Gynecol. and Obstet.*, January, 1930, p. 81), who records an illustrative case, states that tumours composed of structures resembling embryonic and fatty tissue are not frequent, their sites of predilection being the lower extremities. Their malignancy is generally regarded as moderate, because there is usually a well-defined capsule; their growth is slow, and they are freely movable in the surrounding tissues. There is, however, a marked tendency to recurrences, and occasionally metastases occur in the lungs, mediastinum, subcutaneous tissue, and joints. Severe complications may also result from pressure on adjacent vessels and nerves, with subsequent alteration of the organs supplied. Moreover, the occurrence of dilated and tortuous veins over the mass, in the presence of infection, ulceration, abscess, or gangrene, predisposes to sepsis, especially when an operation is performed. Lifvendahl's patient was a woman, aged 41, who noticed small masses in both breasts seven months after giving birth to a healthy child whom she was suckling. Both breasts were amputated, but the fascia, pectoral muscles, and axillary glands were not removed. Three months after the operation metastasis in the lungs developed and death followed. Examination of the tumours showed the typical appearances of liposarcoma. Although sarcoma of the mammary gland occurs in 2 to 3 per cent. of all tumours of the breast, Lifvendahl has been unable to find any other case of liposarcoma of the breast on record.

209. Supracondylar Fracture of the Humerus in Children.

S. C. IVERSEN (*Ugeskrift for Laeger*, November 21st, 1929, p. 1041) has re-examined 37 of the 39 children who were treated at his hospital in the period 1922-27 for supracondylar fracture of the humerus. The treatment of these cases was uniform, and practically every child was admitted as an in-patient on the assumption that the success of treatment largely depended on careful supervision. Of the 37 patients, only 2 were over the age of 12, and there were 20 boys to 17 girls. The left arm was involved in 25 cases, the right in 12. The lesion was an extension fracture in 27 cases, and a flexion fracture in 7; in the remaining 3 cases there was no displacement whatever. The re-examinations were made from one to six years after discharge, when almost complete restoration of the normal appearance of the arm was found in 15 cases. In 20 cases permanent changes—deformity or limitation of the range of movement, or both—were found. While the usefulness of the arm could not be said to be diminished, in some cases the cosmetic value of the arm was reduced by the cubitus varus. In only two cases were there such serious changes (*deformity, limitation of range* of movement, trophic disturbances) that the functional value of the arm was appreciably reduced. The *author concludes* that the general opinion as to the *good functional results* following the treatment of most such cases is justified by his own observations.

210. Haemorrhage from the Male Breast.

B. MARTIN (*Zentralbl. f. Chir.*, January 18th, 1930, p. 130), who records a personal case, states that only fourteen previous examples of haemorrhage from the male breast have been recorded, these being collected in a thesis by Jeran. One patient had a carcinoma, five a benign tumour, and in one no tumour could be found. Martin's patient was a man, aged 57, who had a tumour of the left breast for eighteen months, and a spontaneous blood-stained discharge from the nipple for six months. The breast and axillary glands were excised, and histological examination of the growth showed the condition to be a cystadenoma with carcinomatous degeneration in parts. Recovery ensued.

211. Isolated Fracture of the Transverse Lumbar Process.

G. TOSCHI (*La Chir. degli Organi di Movimento*, November, 1929, p. 286) records, with radiographic illustrations, eighteen cases of processes in the lumbar region, and two where the body of the vertebra was also injured. The accident is not common and is difficult to recognize without a good radiogram. Most of the author's cases were due to direct violence. Of the 34 fractures observed, 10 affected the first lumbar vertebra, 8 the second, 9 the third, 5 the fourth, and 2 the fifth; there were 17 male patients and 2 female. The fragments usually remain in good position, and, if complete rest for two or three weeks is taken, union occurs normally. As regards the symptoms, there is no definite characteristic position; *standing upright* is almost impossible, or sitting without support, the dorsal decubitus being usually preferred. The author discusses the character of the pain, the functional disturbances, late ecchymosis, abnormal mobility of the fragments, and some of the difficulties of radiographic examination in these cases. In treatment, it is added, rigid support of the spine is unnecessary, and may do harm.

Therapeutics.

212. Stramonium in Post-encephalitis.

A. L. JACOBSON and F. EPPLEN (*Journ. Amer. Med. Assoc.*, December 28th, 1929, p. 2027) remark that, except for the limited value of [illegible] in diminishing tremor, no remedial or [illegible] have been in general use for the treatment of the many variations of the Parkinsonian syndrome; not until the various alkaloids of the Solonaceae (a group including belladonna, hyoscyam[illegible] were used was any noteworthy benefit [illegible] mine and small amounts of atropine and scopolamine constitute the chief alkaloids of stramonium leaves. Encouraged by the favourable report of Carmichael and Green on the effectiveness of stramonium in diminishing post-encephalitic rigidity, the present authors undertook to check these observations in a series of hospital and private cases of both the post-encephalitic and the idiopathic paralysis agitans types. Six brief case histories are given, which show the benefits of this treatment. The United States Pharmacopoeia tincture of stramonium was administered orally three or four times daily in doses ranging from 20 to 70 minims. Such symptoms as fatigability, myalgia, ptyalism, hyperhydrosis, and muscular rigidity were invariably relieved; the bradykinesia was improved, and the closely related mental retardation was strikingly affected. Tremor was always benefited, but better results were obtained by the addition of one or two daily doses of scopolamine. No change was noticed in the pareses. Stramonium seemed to be most valuable in the most advanced cases. The authors consider it an excellent palliative remedy for all the sequels of encephalitis, except the pareses. It is of great benefit in idiopathic paralysis agitans, but not so much as in the syndrome of post-encephalitic periods. Very large doses are necessary; toxic manifestations are rare and seemingly transient.

213. Relief of Ocular Pain.

ORBITAL injections of concentrated alcohol in the treatment of painful eyes the vision of which has been completely lost have been advised by Grüter, and favourable results have been reported by many authorities, notably Jaensch and Danis. L. WEEKERS (*Le Scalpel*, January 25th, 1930, p. 85) has confirmed the value of this form of treatment, and has also tried orbital injections of slightly concentrated alcohol in painful ocular affections when vision has not been destroyed. The results in these cases also have been excellent, the effect on the pain being practically immediate. Exceptionally a slight oedema of the pupils and conjunctiva is noticed for two days, but this causes no inconvenience. Though slight diminution of the corneal sensibility persists for a few days, this returns to normal very rapidly, while the relief as regards the pain usually persists. Ophthalmoscopic examination reveals no circulatory trouble in the optic nerve after the injection, and in no case was any harmful effect noted on the vision. Weekers first injects into the orbit 1 c.cm. of a 2 per cent. solution of novocain, as in retro-ocular anaesthesia. The needle is left in place, and after some minutes 1 c.cm. of 20 to 40 per cent. alcohol is injected, the alcohol being still further diluted by the oedema caused by the anaesthetic injection. He emphasizes the importance of having the point of the needle in the centre of the orbit at the moment of injection. If the needle is entered at the level of the external palpebral commissure, it must be pointed upwards and inwards; otherwise the alcohol will be injected against the external orbital wall and a transient paralysis of the right external muscle will result. These injections should, he thinks, be reserved for those ocular affections which cause great and persistent pain, when the usual analgesics prove of no avail. Weekers has employed this method in a considerable variety of morbid conditions, including traumatic lesions, corneal ulcers, neuralgic keratitis, scleritis, and hypertensive iridocyclitis; in the last-named the best results were obtained. Apart from their action on the ocular tension, injections of alcohol do not apparently have any effect on the progress of the disease; patients are relieved by the treatment, but the objective symptoms continue unchanged.

214. Serum Therapy in Typhoid Fever.

J. VERGELY (*Journ. de Méd. de Bordeaux et du Sud-Ouest*, January 10th, 1930, p. 7) has used Rodet's serum with success in six cases of enteric fever during the last two years. He describes two typical cases in detail, and remarks that while the first of these was mild and uncomplicated, the second patient's illness caused great anxiety on account of advanced pregnancy, which terminated in abortion. The author advises that serum should be given as soon as possible after the diagnosis has been established, the usual routine treatment of the disease being followed simultaneously. He thinks it probable that the intestinal ulcers have not healed when the temperature falls, and therefore the dietetic restrictions should not be relaxed. It is advisable to give the first serum injection before the tenth day of the illness; when used towards the fourteenth day it has no effect. A blood culture should be made, therefore, at the commencements of the illness. Vergely has encountered no complication following the injection of serum, except an occasional local urticaria at the site of injection, and one case of generalized urticaria. It is claimed that the treatment shortens greatly the course of enteric fever and appears to prevent the occurrence of complications.

Ophthalmology.

215. Muscle Transplantation for Paralytic Strabismus.

S. R. GIFFORD (*Arch. of Ophthalmol.*, December, 1929, p. 651) considers that the results obtained in paralytic strabismus by advancing the paralysed muscle, combined with tenotomy of the opponent, are usually only temporary; the original squint recurs subsequently. The methods of Hummelsheim, O'Connor, and others merit, he thinks, more frequent application. Good results were obtained in three cases, here reported, in which a modified Hummelsheim operation was performed. In two of these the outer third of the superior and inferior recti were sutured under the tendon of the external rectus, tenotomy of the internal rectus being also performed. In the third case, following an apparent previous section of the muscular portion of the internal rectus, tenotomy of the external rectus was performed, and the inner thirds of the superior and inferior recti were sutured under the insertion of the internal rectus after its adhesions to the globe had been separated. The technique of the operation is described. This method differs from that of Hummelsheim in the free exposure of all three tendons and the insertion of the muscle transplants beneath the tendon of the paralysed muscle. Hummelsheim sutured his transplants under Tenon's capsule over the muscle insertion. Methods employed by other authorities are cited by Gifford, who adds that little reaction followed the operation in the three present cases, and that there was no visible lump beneath the conjunctiva such as is seen after a tuck. The only danger in the operation is that of weakening the vertical recti; this can be avoided by careful exposure of the whole muscle before the outer third is isolated. The method cannot be employed in cases of complete paralysis of the third nerve, since here the vertical recti are paretic. In these cases Weiner's method of suturing the superior oblique to the internal rectus tendon would seem more advisable. Before resorting to operation, sufficient time must have elapsed to eliminate the possibility of recovery of the paretic muscle.

216. Perforating Injuries of the Eye.

H. L. BEGLE (*Amer. Journ. Ophthalmol.*, December, 1929, p. 970) describes briefly some cases of injury to the eye by small particles of steel, with a view to illustrating the direct ratio between the severity of the injury and the size of the foreign body; the influence of the location of the entrance upon the amount of a permanent disturbance; the occasional freedom of the crystalline lens from important opacity secondary to its penetration by fragments of steel; the difficulty of removing these fragments from the crystalline lens when once the capsule has healed; and, finally, the question whether a minute steel particle might ultimately be absorbed and disappear from the tissues of the eye. Begle then records fourteen cases. One patient, a toolmaker, aged 45, was struck in the eye by a foreign body when at work. The injury affected him so little that for four days he did not report the matter, his vision then being only slightly blurred. There was a small crescent-shaped wound of the cornea in the pupillary area, downward and nasalward from the centre of the cornea. Almost directly behind the corneal wound there was a small wound of the anterior capsule of the lens. A minute foreign body lay in the centre position of the lens; the lens substance around it was clear, but the spicule was partly covered by a grey film. The eye was slightly injected. Under cocaine anaesthesia a fragment of the steel was drawn by a magnet through the capsular wound into the anterior chamber. It was allowed to remain there for twenty-four hours to enable the capsular wound to close under the same conditions as when the steel entered the lens. Within five days the patient was back at work, and three years after there was no opacity of the lens substance, though a small capsular opacity was visible at the side of the perforation. In the case of another man, aged 34, who was injured in the right eye by a flying piece of steel, it was several weeks before his vision began to fail, and not until then was the injury recognized as serious. There was a scar in the pupillary zone of the cornea, and a small fragment of steel in the lens cortex. Cataract formation was advanced. It was impossible to draw the steel through the lens capsule since there was no sharp edge, and it could not be made to cut through the capsule. Some weeks later, the eye having become red and irritated, another attempt was made, and succeeded with little difficulty. Begle concludes that if a fragment of steel lies in the lens, and the opacification is not advanced, but there is useful vision, an attempt should be made to remove the fragment as early as possible, for eventually, through siderosis, complete opacification will result. A strong magnet should be used, and repeated attempts be made if necessary. If this is unsuccessful, incision of the anterior capsule is worth trial. It has been assumed that if an *x*-ray examination fails to show the presence of a foreign body complete resting has occurred, and the fragment has become resorbed. Such an assumption, Begle maintains, is not justified by a negative *x*-ray examination alone. He agrees that a small foreign body may pass entirely through the lens and yet the patient may retain useful industrial vision; the reason given is that opacification of the lens is limited to a punctate opacity at the point of entrance in the anterior capsule and a disc-shaped opacity of the posterior lens capsule at the point of exit.

217. Optic Neuritis after Whooping-cough.

G. H. HOGG (*Med. Journ. of Australia*, August 3rd, 1929, p. 169), who recorded a case of optic neuritis in whooping-cough (see *Epitome*, October 1st, 1927, para. 300), reports another example of this rare complication in a girl aged 3 years and 5 months. When examined five months after the onset of whooping-cough she was quite blind in her left eye, and with the right eye she could only see large toys at a distance of 30 to 40 cm. There was bilateral optic atrophy, most marked in the left disc. Slight improvement of the vision of the right eye occurred after two months' treatment with strychnine, but the appearance of the discs remained the same. Hogg has collected seven other cases of optic neuritis in whooping-cough in patients aged from 3 to 40; in five of these recovery took place, and in two atrophy supervened.

218. Malaria Therapy in Interstitial Keratitis.

IRENA MRAZOVA (*Bratislavské Lekarské Listy*, December, 1929, p. 1259) tried therapeutic inoculation with malaria in twelve cases of interstitial keratitis, combining it with preliminary and subsequent antisyphilitic treatment. The subjective and objective symptoms were relieved during the attack of malaria, but recurred and even became worse subsequently; appreciable improvement was noted in only two cases. The malaria did not prevent recurrences or have any prophylactic effect, and the Wassermann reaction remained positive throughout.

Obstetrics and Gynaecology.

219. The Radium Dosage for Menorrhagia.

N. ASHERSON (*Journ. Obstet. and Gynaecol. of the British Empire*, Winter, 1929, p. 778) summarizes the results of radium treatment in 98 cases of menorrhagia not due to uterine fibroid or malignant disease, during five years at University College Hospital. Of these, 66 were cases of menorrhagia of the menopause, and amenorrhoea resulted in all but one case. The dose, which had to be repeated in only six instances, was as a rule 1,200–1,800 milligram hours of radium element. After dilatation and curetting under general anaesthesia, a tube of 50 mg. of element in a platinum container with walls 0.5 mm. thick, and covered by a 2 mm. rubber screen, was left in the cavum uteri up to thirty-six hours. No case receiving 1,800 milligram hours of element dosage required a second application. Twenty-three patients with essential menorrhagia (intractable menorrhagia apart from the menopause and unaccompanied by clinically detectable pelvic abnormality) were treated by one or two radium applications. Although only one failed to show improvement, in only about one-fifth did complete amenorrhoea ensue.

One patient, becoming pregnant sixteen months later, was delivered of a living child which had double inguinal hernia. By subdivision of the patients treated into age groups the conclusion is drawn that in patients between puberty and the menopause the size of the radium dose required to produce amenorrhoea is inversely proportional to the age of the patient. It is also noted that of 80 cases of menopausal haemorrhage treated by radium malignant disease of the uterus did not supervene in a single case. It is therefore suggested that in the radiotherapeutic induction of a premature menopause a prophylactic against carcinoma of the cervix has possibly been found.

220. Anaemia in Pregnancy.

C. E. GALLOWAY (*Journ. Amer. Med. Assoc.*, November 30th, 1929, p. 1695) gives results of blood examinations made on 382 pregnant women, from which it appears that in a large number (65 per cent.) of pregnant women anaemia is present, and that it becomes more marked as pregnancy advances. The degree of anaemia was never severe; no examination revealed a haemoglobin percentage lower than 50, and the lowest average percentage for any period was 66; the lowest red cell count recorded is 3.2 million per c.mm., and the lowest average during the third trimester was 3.87 million per c.mm. Galloway found no difference in the tendency towards anaemia between multiparae and primiparae. Only 19 per cent. of the patients received treatment other than diet, with simple iron and liver preparations. It was found that liver therapy was not so beneficial as iron, or a combination of iron and arsenic. Seventy-four cases did not respond to diet and tonics, but twelve to twenty exposures to ultra-violet rays, at two-day intervals, gave satisfactory improvement in 51 cases. The author adds that the important treatment of anaemia in pregnancy, as in all forms of anaemia, is the elimination of foci of infection, such as pyelitis and infected teeth and tonsils.

221. The Low Caesarean Operation.

H. MAGOS (*Bruxelles-Méd.*, December 1st, 1929, p. 123) discusses his experience of treating 21 patients by the low Caesarean operation preceded by trial labour. He considers that the great advantage of this method lies in the fact that the trial labour may terminate in a normal delivery. If an operation is found to be necessary there is less danger of infecting the peritoneum in the low operation, and also there results a more resistant scar than in the high operation. In cases of contracted pelvis he finds it advisable to let labour proceed, and to follow the progress of the head by abdominal palpation. The bag of membranes does not hinder engagement except in hydramnios. Rupture of the membranes should be avoided. If after six to eight hours of intense labour the head still floats at the superior strait, in spite of an advanced dilatation, it becomes necessary to decide whether the state of the mother or child demands surgical intervention. If the membranes are ruptured when the patient comes under observation the trial labour should not be prolonged. The most important point in the preparation of the patient is catheterization of the bladder. Even with this precaution the bladder may not contract sufficiently to allow an incision to be made in the lower segment, in which case a high Caesarean operation has to be performed. Occasionally the foetus may have to be extracted through the incision by means of forceps. Post-operative treatment should be devoted to care of the bladder. Patients are said to suffer no shock after this operation, and to run very little temperature.

Pathology.

222. Development of Immunity in Experimental Typhus Fever.

Y. FUKUDA (*Zentralbl. f. Bakt.*, December 16th, 1929, p. 83) cites evidence that in guinea-pigs immunity to typhus fever always follows an active infection with the virus, and that it may be the sequel of a symptomless infection. In his first experiment [illegible] were injected intraperitoneally with [illegible] virus-containing brain from a "passage" guinea-pig on the fourth day of fever. The twenty animals developed fever six or seven days later, the temperature rising above 39.2° C.; they remained febrile for a week and then recovered. A fortnight after the end of the fever each animal was injected intraperitoneally with one-tenth of a virulent brain; none of the animals developed a temperature during the succeeding three weeks, and were therefore regarded as having acquired an active immunity. In his second experiment four groups of four guinea-pigs were injected subcutaneously with 5 c.cm. of immune serum, taken from guinea-pigs fourteen days after the end of a febrile attack. On the following day Group I received 0.0001, Group II 0.001, Group III 0.01, and Group IV 0.1 of virulent brain. A control guinea-pig was included in each group, and received virus but no serum. In the first group the animals remained afebrile, and when reinjected eight weeks later with 0.1 virulent brain all gave a typical febrile reaction. In the second group there was no fever after either the primary or the secondary injection. In the third group three animals developed some fever after the first injection, but did not respond to the second. In the fourth group all animals reacted to the first but not to the second injection. The control animals all reacted to the first but not to the second injection. The blood of Group I animals, taken on the fourteenth day after the first injection, proved to be avirulent, while that of Group II was virulent. The author explains these results as follows. In Group I the virus was destroyed by the immune serum; no true infection developed, and the animals were therefore susceptible to a second injection. Group II developed a symptomless infection, sufficient, however, to produce an active immunity. In Group III the serum was not able to suppress all symptoms of disease, and in Group IV it had no appreciable effect on the course of infection; in both groups active immunity developed as the result of infection. The author concludes that for a given dose of virus there is a corresponding dose of serum which, while suppressing the actual symptoms of disease, allows the virus to develop in the body and to call forth an active immunity in the host.

223. The Glycogen Content in Heart Muscle.

A. COSTA (*Lo Sperimentale*, December 30th, 1929, p. 605), using the micrometric histological methods of Tangl and the chemical analytical procedure of Polenski, has estimated the amount of the glycogen content in the heart muscle of man in cases of spontaneous cardiac hypertrophy, and in the experimental cardiac hypertrophy of rabbits produced by the technique of Rosenbach. The operation was performed on twenty rabbits, and a number of healthy rabbits were examined as controls. The results of Costa's observations show that in rabbits the diameter of the cardiac muscle fibre was increased in hypertrophy, the percentage of glycogen was lowered, but the total glycogen content was unaltered. Regarding the glycogen content as an index of muscle metabolism, it appears that disintegration and synthesis proceed *pari passu*, and the reserve glycogen, which remains unchanged in amount, is a phase of metabolic equilibrium. From stained sections it was discovered that the distribution of the glycogen is unequal and variable in site; it is deposited in the sarcoplasm and in the perinuclear plasm of the muscle cells. It is added that the specimens of muscle obtained from the left ventricle in human cases at necropsies give results which are subject to the correction of error from the rapid degeneration of glycogen after death.

224. Immunizing Value of Heated Vaccine Virus.

H. ZEHNDER (*Zeit. f. Immunitätsforsch.*, December 30th, 1929, p. 365) has endeavoured to repeat Nakagawa's experiments on the immunizing effect of a vaccine made from heated vaccinia virus. The cocto-immunogen was prepared by heating raw vaccine lymph, diluted one-fifth, for forty minutes to 98°–99° C., centrifuging, and using the supernatant fluid. In some experiments the centrifuged deposit was used. Rabbits were inoculated daily for eight to ten days into the left testicle with increasing amounts of the cocto-immunogen; fifteen to thirty days after the last injection the animals were injected into both testicles, into the cornea, and into the skin with diluted living vaccine virus. On the day previous to the infection blood was taken from the ear vein, and the serum was tested for viricidal power. The results showed that the left testicle, into which the heated vaccine had been introduced, was insusceptible to living virus; the right testicle, however, reacted to a greater or less degree, while the skin and cornea reacted like those of control rabbits. No viricidal bodies were found in the serum of the vaccinated animals. Examination of the testicles showed that even in the insusceptible left testicle the virus was present a week after inoculation. In a second group of control rabbits receiving a single dose of living vaccine two to four weeks before the test dose, the testicles, skin, and cornea all proved insusceptible to the second infection, the serum contained viricidal antibodies, and no virus was found in the testicles. Rabbits treated by eight to ten intratesticular injections of ox serum or of muscle extract behaved in the same way as those receiving the cocto-immunogen. The author therefore concludes that the insusceptibility of the treated testicle in rabbits inoculated with the cocto-immunogen is merely the result of a non-specific local increase in tissue resistance, and is not due to a true specific immunity.

THE LANCET AND

RYVITA 1930 TALKS No. 1.

RYVITA
CRISPBREAD

"The Lancet" in its Reports and Analytical Records has said of Ryvita Crispbread:—

"There is more character in the flavour of Rye than of wheat, and the food value of the former (rye) needs no comment.

"On analysis (of Ryvita) the following results were obtained:—

	Per cent.
Carbohydrates, altered starch, hemicellulose, etc.	74.8
Protein	11.6
Moisture	9.0
Ash	1.8
Fat	1.3
Fibre	1.5

Calorie value per lb., 1662.

"Ryvita Crispbread, which keeps well and does not readily become 'slack,' is easily masticated and digested, and is a useful and palatable addition to the diet. The calorie value shows it to be a concentrated form of food."

* * *

Ryvita Crispbread is a most appetising form of bread—crisp, crunchy, and delicious. It is made of pure, crushed, wholegrain rye, and is a complete cereal food, not only because of its perfectly balanced food elements but also because, mechanically, its natural fibrous form is an actual aid to the functional processes of digestion, assimilation, and elimination.

Ryvita is rich in the natural organic salts of iron, phosphorus, and lime, and is therefore a valuable body-building food. It is balanced by its own B Vitamin, because owing to a difference in the structure of rye grain the germ cannot be lost in the milling as it so often is from wheat or oats.

Many Doctors make Ryvita Crispbread their own daily bread, and recommend it enthusiastically to their patients. Ryvita is definitely indicated as an item of the dietary in treatment of disorders arising from digestion, constipation, or malnutrition.

It is usual to suggest that the patient begin by eating two or three slices of Ryvita with one meal each day.

We shall be very pleased to send Free Samples and full particulars to any interested Member of the Profession.

Dermatoses

Physicians will find in Emol-Keleet an effective adjuvant in the treatment of pruriginous and eruptive dermatoses. Emol-Keleet is most comforting to the patient, since its sedative action affords immediate relief from the distressing itching.

Emol-Keleet

As a protective dressing in the treatment of Eczema, and for allaying the prurigo accompanying Scarlet Fever and Measles, it can always be relied upon to bring immediate relief.

In infantile cases especially, the value of Emol Keleet in clearing up rashes is most marked.

Samples free to the Medical Profession on request.

FASSETT & JOHNSON, Ltd., 56, Clerkenwell Road, London, E.C.1.

This preparation is now obtainable in 5-oz. bottles.

"MIST. PEPSINÆ CO. C. BISMUTHO"

(HEWLETT'S).

This preparation is also supplied "sine Opio," the dose and price remaining the same.

INTRODUCED AND PREPARED ONLY BY

C. J. HEWLETT & SON, Ltd., 35 to 42, Charlotte Street, LONDON, E.C.2.

Also in exactly similar form and price—

SOLID IODINE

A Remarkable advance in the presentation of H_2O_2

Owing to the rapidity in which H_2O_2 ordinarily loses its strength, it has not usually been practicable to carry a supply about without risk of frequent replacement; also, of course, of breakage.

Now a new process has been introduced of presenting Peroxide of Hydrogen in a solidified form, so as to enable it to be included conveniently in the physician's or surgeon's every day case of instruments, etc.

This Solidified Peroxide of Hydrogen is known under the trade name of 'Peroxtik.' It is guaranteed to maintain its original 10-volume strength for a reasonable period.

A full-size tube of this new product will gladly be sent to the Medical Profession FREE on application to the Medical Dept., Messrs. ARTHUR H. COX & CO., LTD., 93, Lewes Road, Brighton, or can be purchased from the usual sources, at the cost of 1/3.

'Peroxtik'

SOLIDIFIED PEROXIDE OF HYDROGEN

in neat, handy glass tubes.

FOR INTERNAL TREATMENT OF GONORRHŒA, URETHRITIS, AND OTHER AFFECTIONS OF THE GENITO-URINARY TRACT.

SANTAL MIDY CAPSULES have been prescribed with uniform success for over thirty years. Distilled from carefully selected Mysore Sandal Wood, the oil is bland and remarkably

FREE FROM THE IRRITANT AND NAUSEATING EFFECTS

which are provoked by many preparations.

There is marked absence of gastric and other disturbances, diarrhœa and skin eruptions. Its mild chemotactic properties permits its administration in relatively large doses without fear of too violent reaction or intolerance.

SANTAL MIDY CAPSULES may be prescribed and relied upon in all stages of Gonorrhœa and in other forms of Urethritis and affections of the Genito-Urinary tract.

The Capsules contain 5 drops, and usually 10 to 12 are given daily in divided doses.

Prepared in the Laboratoire de Pharmacologie Générale, 8, Rue Virienne, Paris, and sold by most Chemists and Wholesale Druggists throughout the World.

U.K. Agents: WILCOX, JOZEAU & CO., 15, Gt. St. Andrew St., W.C.2

FOR DEAFNESS
Doctors prefer "ARDENTE" because

1. It is individually fitted to suit the case for young, middle-aged, or old.
2. It is simple and true-to-tone, and leaves the hands free.
3. It removes strain, thus relieving head noises.
4. It conveys sounds from all ranges and angles.
5. It is entirely different, uncopyable, and carries a guarantee and service system.
6. It is suitable for "hard of hearing" or acutely deaf.
7. It is helpful for conversation, music, wireless, home, office, public work, and sports

"ARDENTE" STETHOSCOPE.
Mr. R. H. Dent makes a Stethoscope specially for members of the medical profession suffering from deafness. Many are in use, and excellent results are reported on the latest, as evidenced by the interest shown at the last B.M.A. Meeting.

MEDICAL REPORTS.
Commended by all leading medical journals.—Mr. Dent will be happy to send full particulars and reprints on request.

Salt and Son Ltd.

SALT'S PATENT VARUS BOOT AND LEG INSTRUMENT

A Typical Case of Talipes Varus.

Illustrations, reproductions of photographs, of a boy with and without Salt's Patent Varus Boot and Leg Instrument.

Photographs were taken when boot, etc., were first applied.

The first illustration shows how the ankle goes over outwardly, so that when standing weight would accentuate mal-position.

The second illustration shows Varus Boot and Instrument applied.

It will be seen that the front of the foot has been everted by boot, the ankle being held in correct position by "T" Strap fastening over instrument.

Salt's Patent Varus Boot and Leg Instrument has been successful in over 2,000 cases of Talipes Varus.

Write for full particulars.

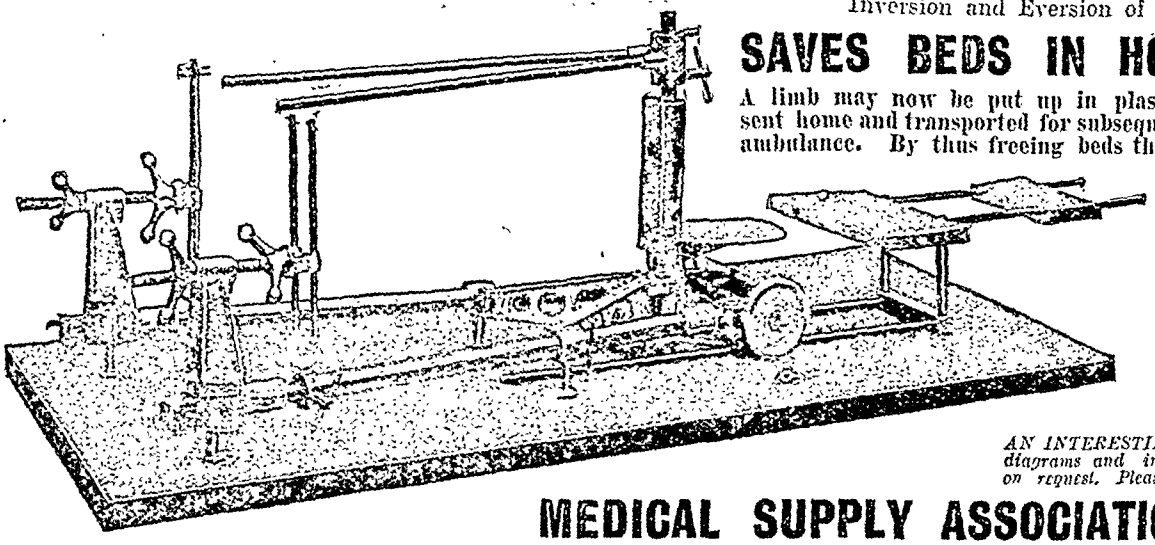
ESTABLISHED 1793



An IMPROVED and MODIFIED

Portable Traction Apparatus

An exceedingly efficient and convenient apparatus for putting up in plaster the lower limbs or trunk; also when applying bone plates or Parham and Martin's Bands to long bones of the lower extremity. Provides the more essential movements of expensive and bulky Orthopædic tables at a fraction of the cost.

Quickly adaptable for the following positions:

Extension of whole lower limbs.
Movements about hip-joint:
Abduction to any degree—
Hyperextension—Flexion—
Internal and External Rotation.
Flexion of knee-joint.
Inversion and Eversion of foot.

SAVES BEDS IN HOSPITALS

A limb may now be put up in plaster, the patient sent home and transported for subsequent treatment by ambulance. By thus freeing beds this new apparatus saves its cost many times over.

Folds compactly for storage or transit in plywood case 35 in. × 15 in. × 11 in.

THE POSTAL ACCOUNT

It is often supposed that to live a long way from the nearest branch of a bank, or to be constantly unable to go to the bank in person, is a handicap to the enjoyment of the full advantages which, it is admitted, a banking account offers. Perhaps it is assumed that to conduct an account by post involves 'more letter writing', or is costly, or is not welcomed by the Bank. It is the aim of the Westminster Bank to dispel such misconceptions by a leaflet entitled *The Postal Account*, which explains the convenience of the method, and offers some clear suggestions.

The Secretary of the Bank will be pleased to send a copy on application

WHOOPING COUGH

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing, and given a little at frequent intervals.
There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.
Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

ALLEN & HANBURYS, LTD. :: :: Lombard Street, London, E.C.3.

for Accurate Abdominal Support and Comfort

EXTRACT FROM THE "BRITISH MEDICAL JOURNAL," DEC. 10th, 1927—

"Visceroptosis is the cause of so much discomfort and ill-health ... and an ill-fitting or wrongly applied belt or corset may aggravate rather than diminish the subjective effects of this condition.... MADAME ROSE has for many years devoted special attention to this problem, and we have good reason to believe that she has given help and comfort to a considerable number of sufferers. We have received assurances from medical men, who have sent patients to her, that she gives personal attention to each patient, that she takes great care in adapting and adjusting the support to the particular needs of the case."

FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an *Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus*, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital *is beautifully situated in a Park of 330 acres*, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital *there are cricket grounds, football and hockey grounds*, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, *and facilities are provided for handicrafts*, such as carpentering, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

Tel.: 64117. *For terms etc., apply to the Medical Superintendent.*

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 *Ashton-in-Makerfield.*

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.

FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 5 guineas a week. For further particulars apply to—

Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of *the South Devon Coast*. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.

Telephone: *Teignmouth* 289.

City of Carlisle.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

The Council of the City and County Borough of Carlisle invite applications for the appointment of Assistant Medical Officer of Health at a salary of £750 per annum. The duties of the appointment are principally those connected with the diagnosis and treatment of Tuberculosis and the medical inspection and treatment of school children, including Eye work and Refractions.

Candidates must not be more than 40 years of age, and must be fully qualified and registered Medical Practitioners holding the Diploma in Public Health or an equivalent qualification.

Candidates must either have held a previous appointment as Tuberculosis Officer with the approval of the Minister of Health, or should, subsequent to qualification,

(1) Have had at least three years' experience in the practice of their profession;
(2) Have spent in general clinical work a period of not less than 18 months, of which not less than six months have been spent in a Hospital as resident officer in charge of beds occupied by general medical or surgical cases; and
(3) Have received special training, for a period of not less than six months, in the diagnosis and treatment of Tuberculosis.

The gentleman appointed will be required to devote the whole of his time to the duties of the office, to reside in the City, and will not be allowed to engage in private practice.

The appointment is an established post under the Local Government and Other Officers Superannuation Act, 1922, and the gentleman appointed will be required to pass a medical examination, and contribute 5 per cent. of his salary to the Superannuation Fund.

Applications, stating age, qualifications, and experience, accompanied by copies of not more than three recent testimonials, and endorsed "Assistant Medical Officer of Health," must reach me not later than the first post on Friday, March 14th.

Canvassing, either directly or indirectly, is prohibited.

Applicants may, if they desire, forward sealed copies of their applications and testimonials to the members of the Selection Committee, a list of whose names will be supplied by the undersigned, upon request.

Town Clerk's Office, Carlisle. FREDK. G. WEBSTER, Town Clerk.

February 24th, 1930.

The Southampton Children's HOSPITAL AND DISPENSARY FOR WOMEN. (45 Beds.)

Secretaries and Registered Office: Millar, Thomson & Dunlop, C.A., 113, St. Vincent Street, Glasgow.

ANNUAL SUBSCRIPTION £1. ENTRANCE FEE 10/-.

No entrance fee to those joining within 12 months of obtaining qualification. Benefits include defence of claims for alleged negligence in professional work, including indemnity of £2,500 and costs, and advice on professional difficulties.

Particulars and forms of application can be obtained from the Secretaries at the above address.

City and County of Kingston-upon-Hull.

APPOINTMENT OF MEDICAL SUPERINTENDENT.

The Corporation invite applications for the appointment of a Medical Superintendent of the CITY FEVER HOSPITAL and the SANATORIUM at a commencing salary of £800, rising, subject to satisfactory service, by annual increments of £25 to a maximum of £1,000 per annum, together with housing accommodation, rates, and lighting. The age of candidates is not to exceed 40 years.

At present the Fever Hospital contains 112 beds and the Sanatorium 132 beds, but extensions are contemplated, and it is proposed later to build an Orthopædic Hospital on the site, of which the Medical Superintendent will have administrative charge.

Candidates should either have held an appointment of Medical Superintendent of a Sanatorium with the approval of the Ministry of Health, or should, subsequent to qualification,

(1) Have had at least three years' experience in the practice of their profession,

(2) Have spent in general clinical work a period of not less than 18 months, of which not less than six months have been spent in a hospital as resident officer in charge of beds occupied by general medical or surgical cases and gynæcological or surgical cases, and

(3) Have received special training, for a period of not less than six months, in the diagnosis and treatment of Tuberculosis.

They should further possess a wide clinical knowledge of infectious diseases.

The gentleman appointed, who should be married, will be under the administrative control of the Medical Officer of Health.

As the post is a designated post under the Local Government and Other Officers Superannuation Act, 1922, the successful candidate will be required to undergo a medical examination.

Forms of application, which are obtainable from the undersigned, should be returned so as to be received not later than March 8th.

Health Department, Guildhall, Hull. W. M. FRAZER, Medical Officer of Health.

February 18th, 1930.

City and County of Kingston-upon-Hull.

APPOINTMENT OF TUBERCULOSIS OFFICER.

The Corporation invite applications for the post of Clinical Tuberculosis Officer at a commencing salary of £800, rising, subject to satisfactory service, by annual increments of £25 to a maximum of £1,000 per annum. The age of candidates is not to exceed 40 years.

Candidates should either have held a previous appointment as Tuberculosis Officer with the approval of the Ministry of Health, or should, subsequent to qualification,

(1) Have had at least three years' experience in the practice of their profession,

(2) Have spent in general clinical work a period of not less than 18 months, of which not less than six months have been spent in a hospital as resident officer in charge of beds occupied by general medical or surgical cases, and

(3) Have received special training, for a period of not less than six months, in the diagnosis and treatment of Tuberculosis.

The gentleman appointed will rank as a Senior Assistant Medical Officer of Health, and will work under the general administrative control of the Medical Officer of Health.

As the post is a designated post under the Local Government and Other Officers Superannuation Act, 1922, the successful candidate will be required to undergo a medical examination.

Forms of application, which are obtainable from the undersigned, should be returned so as to be received not later than March 8th.

Health Department, Guildhall, Hull. W. M. FRAZER, Medical Officer of Health.

February 18th, 1930.

Willesden Urban District Council.

HEALTH DEPARTMENT.

APPOINTMENT OF DENTISTS.

The Willesden Urban District Council require the services of Two Dentists.

The duties attached to this post include the Dental Inspection and Treatment of School Children and the Dental Inspection and Treatment of Expectant and Nursing Mothers, and Children under five years of age, and such other duties as the Council or Medical Officer of Health may require to be undertaken.

The Dentists work under the administrative control of the Medical Officer of Health.

The appointments are terminable by a month's notice on either side, is subject to the Council's regulations concerning Officers of the Council, and to the provisions of the Local Government and Other Officers Superannuation Act, 1922.

The age of candidates should not exceed 40 years, unless they are at present occupying an established post under the Act.

The successful applicants will be required to pass a medical examination.

Candidates must possess a registrable qualification in Dentistry, and devote their whole time to the duties of the office.

Commencing salary £420, rising by four annual increments to £517 10s., with Civil Service bonus in addition, which bonus fluctuates according to the rise or fall in the cost of living, revision being made every six months—namely, March 1st and September 1st. At the present time the commencing salary and bonus is at the rate of £572 6s. 4d. per annum.

Travelling expenses within the district paid by the Council.

Application forms may be obtained on application by letter (enclosing stamped addressed envelope) to the Medical Officer of Health, Health Department, 54, Winchester Avenue, Kilburn, N.W.6, and should be returned to him duly filled in by applicant, together with copies of three testimonials, not later than Friday, March 7th.

Town Hall, Dyne Road, N.W.6. E. A. PRATT, Clerk of the Council.

Willesden Urban District Council.

APPOINTMENTS OF ONE PART-TIME ANÆSTHETIST. ONE PART-TIME OCULIST.

Applications are invited for the above appointments.

Part-time Anæsthetist.—The salary attached to the post of Part-time Anæsthetist is at the rate of £300 per annum, and the Anæsthetist will be required to attend four times per week at the Willesden Health Centres for the purpose of administering anæsthetics in connection with dental cases.

Part-time Oculist.—The salary attached to the post of Part-time Oculist is at the rate of £225 per annum, and the Oculist will be required to attend three times per week at the Willesden Health Centres to carry out refraction work mainly in connection with school children.

Further particulars of the above appointments can be obtained from the Medical Officer of Health, Health Department, 54, Winchester Avenue, Kilburn, N.W.6.

Applicants should state their qualifications, age, and experience.

All applications should reach the Medical Officer of Health not later than 9 a.m. on Friday, March 7th.

Town Hall, Dyne Road, Kilburn, N.W.6. E. A. PRATT, Clerk to the Council. February 15th, 1930.

Scarborough Hospital and DISPENSARY. (70 Beds.)

Wanted, May 1st, Two HOUSE SURGEONS (male or female). Duties include Home Visiting. Salary £126 per annum, with board, residence, etc. Appointment for six months. Applications, stating age, with copies of testimonials and essential particulars, to be sent to the undersigned by March 17th, from whom further particulars may be obtained.

J. DOUGLAS MUNBY, Hon. Secretary.

City of Plymouth.

MEDICAL SUPERINTENDENT.

MENTAL HOSPITAL.

The Visiting Committee invite applications for the post of Medical Superintendent to the Plymouth City Mental Hospital, Ivybridge, near Plymouth.

Candidates must be duly registered Medical Practitioners who have had experience in the management of a Mental Hospital.

The salary will be £750 per annum, rising by £50 per annum to £1,000 per annum, and the Committee will provide, in addition, a furnished house at Blackadon (where the Medical Superintendent will be required to reside), and coal, light, laundry, vegetables, and dairy produce free. The total value of these emoluments is estimated, and will be taken for the purpose of the Asylum Officers Superannuation Act, 1909, as being worth £200 per annum.

The person appointed must devote his whole time to the duties of the office, and such duties will include those of Certifying Officer under the Mental Deficiency Acts and also (if required) of Medical Officer in Charge of the Mental Clinic.

Canvassing, directly or indirectly, will be a disqualification.

Forms of application and further particulars may be obtained on application to the undersigned.

Applications to be sent to the undersigned, endorsed "Medical Superintendent, Mental Hospital," not later than March 1st.

Dated this 6th day of February, 1930.

Municipal Offices, Plymouth. R. J. FITTALL, Town Clerk.

City of Exeter.

ASSISTANT TUBERCULOSIS OFFICER AND ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited for the joint appointment of Assistant Tuberculosis Officer and Assistant Medical Officer of Health for the City and County of the City of Exeter, at a salary of £600 per annum, rising to £700 per annum by four annual increments of £25, subject to deductions in accordance with the provisions of the Local Government and Other Officers Superannuation Act, 1922.

Applicants must be registered Medical Practitioners of not less than three years' standing, and possess the Diploma of Public Health. Special experience with regard to Tuberculosis is essential.

Although the work will be largely in Tuberculosis, the successful candidate will also be required to take a part in the general work of the Department, under the supervision of the Medical Officer of Health.

Applications, endorsed "Assistant Tuberculosis Officer," accompanied by three testimonials, must be received by me not later than Thursday, March 20th.

Application forms and condition of appointment may be obtained at my office, and further particulars, if required, from the Medical Officer of Health.

H. LLOYD PARRY, Town Clerk.

February 20th, 1930.

County of London.

The LONDON COUNTY COUNCIL invites applications for appointment as EIGHTH ASSISTANT MEDICAL OFFICER (men) in its Mental Hospital Service. Candidates must be under 35 years of age and be registered to practise both in Medicine and Surgery in England. Salary £445 a year, rising by annual increments of £25 to £570 a year. No emoluments. Charges made for board, lodging, etc. (at present £2 9s. a week) if required to be resident. Candidates appointed will be pensionable under the Asylums Officers Superannuation Act, 1909. Form of application, on which full particulars are given, can be obtained from the Acting Chief Officer, Mental Hospitals Department, The County Hall, Westminster Bridge, S.E.1. Applications must be received by Thursday, March 6th.

Canvassing disqualifies.

MONTAGU H. COX, Clerk of the London County Council.

COLONIAL MEDICAL SERVICES.

Vacancies exist at present for Medical Officers in:—

(*a*) **THE WEST AFRICAN MEDICAL STAFF;**
(*b*) **THE EAST AFRICAN MEDICAL SERVICE;**
(*c*) **THE MALAYAN MEDICAL SERVICE.**

Qualifications.

Applicants must be British subjects of European parentage and between 22 and 35 years of age. They must possess a double qualification and be on the British Medical Register. Preference will be given to candidates who have held hospital or public health appointments or who have special knowledge of anæsthetics, radiology, surgery, medicine, ophthalmology, gynæcology and midwifery, diseases of the ear, nose and throat, venereal diseases, etc.

Courses of Study.

Selected candidates will normally be required to take a special course of study in tropical medicine and hygiene either at the London School of Hygiene and Tropical Medicine or at the Liverpool School of Tropical Medicine, or at the University of Edinburgh, before taking up their appointments. Tuition fees and the usual training allowance will be paid from Government funds.

Further particulars and forms of application may be obtained, on application in writing, from the PRIVATE SECRETARY (APPOINTMENTS), COLONIAL OFFICE, 2, Richmond Terrace, Whitehall, London, S.W.1.

County Borough of Hastings.

PUBLIC HEALTH DEPARTMENT.

DEPUTY MEDICAL OFFICER OF HEALTH AND DEPUTY SCHOOL MEDICAL OFFICER.

The Council invite applications for the appointment of Deputy Medical Officer of Health and Deputy School Medical Officer (male or female) at a salary of £600 per annum, rising by annual increments of £25 to £700 per annum, with an allowance of £10 per annum for local travelling expenses.

Applicants must be Medical Men or Women, under 40 years of age, holding a special qualification in State Medicine or a Diploma in Public Health, with not less than three years' experience after qualifying.

Preference will be given to applicants who have had experience of school medical work, infectious diseases and other branches of public health work, and have held a resident Hospital appointment.

The person appointed will work under the direction and control of the Medical Officer of Health and will be employed mainly in the School Medical Service, but will also assist the Medical Officer of Health in other departments of the Health Services of the Corporation.

The person appointed will be required to reside within the Borough of Hastings, to devote the whole of his or her time to the duties of the office, to contribute to the Council's Superannuation Scheme, and to pass a medical examination.

Canvassing Members of the Council will be a *disqualification.*

Applications, on forms to be obtained from me, must be addressed to me, endorsed "Deputy Medical Officer," at the Town Hall, Hastings, not later than March 15th.

D. W. JACKSON, Town Clerk.

Eastern Dispensary, Leman Street, E.1.

Applications are invited for the post of OPHTHALMIC SURGEON to this Institution. Attendance alternate Tuesdays at 5.30 p.m. Candidates must be Fellows or Members of a Royal College of Surgeons in the United Kingdom, or Masters in Surgery of a British University. There is an honorarium attached to the post.

GEORGE W. ILSLEY,
February 25th, 1930. Secretary.

County Borough of Southampton.

ASSISTANT MEDICAL OFFICER OF HEALTH.

Applications are invited for the position of Assistant School Medical Officer at a salary of £600 per annum.

The gentleman appointed will hold office during the pleasure of the Council, and the appointment will be determinable by two months' notice on either side. He will be required to carry out duties in connection with the Medical Inspection and Treatment of School Children, the Public Health Acts, Mental Deficiency Acts, 1913-27, Maternity and Child Welfare and *Venereal Disease* work, etc.

He must devote the whole of his time to the duties of the office and the performance of such other duties as may be required under the direction of the Medical Officer of Health.

The appointment will be subject to the approval of the Board of Education and the Minister of Health.

The Local Government and Other Officers Superannuation Act, 1922, will be applicable to the appointment, and contributions to the Superannuation Fund will be deducted from the salary. The selected candidate will be required to pass a satisfactory medical examination.

Forms of application may be obtained from the Medical Officer of Health, Municipal Offices, Southampton.

Applications on the prescribed form, endorsed "Assistant Medical Officer of Health," stating age, qualifications, experience, etc., together with copies of not more than three recent testimonials, must be delivered at the Town Clerk's Office, Municipal Offices, Southampton, on or before March 15th.

R. RONALD H. MEGGESON,
February 24th, 1930. Town Clerk.

Bedford County Hospital.

APPOINTMENTS.—Contd.

St. Bartholomew's Hospital, ROCHESTER.
(Rochester, Chatham, Gillingham, and District.)
(126 Beds.)

The House and Finance Committee invite applications for the post of HOUSE PHYSICIAN, vacant on April 1st.
Candidates must be unmarried, qualified, and registered Medical Men. The appointment is for six months, and the salary is at the rate of £175 per annum, with board, residence, and laundry. The officer appointed will have charge of the Medical beds. Some knowledge of Ophthalmic work is desirable.
Applications, stating age, qualifications, and experience, accompanied by copies of three recent testimonials, to be sent to the Secretary not later than March 13th.

Diploma in Advanced Psychology (FOR NURSES).

Under the auspices of the British College of Nurses, an intensive course of Fifteen Lectures on Psychology, Morbid Psychology, and the nursing of the commoner Mental and Nervous Disorders, will be held on Tuesday evenings, commencing on March 18th, at 8 o'clock.

Full particulars may be obtained from the Secretary, British College of Nurses, 39, Portland Place, W.1.

Connaught Hospital
(100 Beds)
FOR WALTHAMSTOW, WANSTEAD, AND LEYTON, Orford Road, E.17.

Applications are invited for the undermentioned posts:

(1) SENIOR RESIDENT MEDICAL OFFICER (male). Salary £150 per annum.
(2) RESIDENT HOUSE SURGEON (male). Salary £100 per annum.
(3) RESIDENT HOUSE PHYSICIAN (male). Salary £100 per annum.

Appointment No. 3 to date from April 1st, and appointments Nos. 1 and 2 to date from May 1st. All appointments to be for a period of six months, with board, residence, and laundry provided.

Applications, with three testimonials (or copies), should be sent to the Secretary, to reach him as follows: No. 3 not later than March 14th; Nos. 1 and 2 not later than April 16th.

Herefordshire County Council;
ROSS URBAN AND LEDBURY AND ROSS RURAL DISTRICT COUNCILS.

ASSISTANT COUNTY MEDICAL OFFICER and MEDICAL OFFICER OF HEALTH.

The Herefordshire County Council, the Ross Urban, and Ledbury and Ross Rural District Councils require a Medical Officer who will act as an Assistant County Medical Officer and a Medical Officer of Health to serve the area of the District Councils named, and to be responsible for the Poor Law Institution at Ross.

Salary £685 per annum, with travelling expenses.

Applications must be received by Saturday, March 15th, by the Clerk of the County Council, Shirehall, Hereford.

London Hospital, E.1.

Applications are invited for the post of DIRECTOR of the Department for Venereal Diseases. Candidates must be fully qualified and must possess special knowledge and experience of the diagnosis and treatment of these diseases.

The salary for the post is £800 a year, and the Director will be required to devote not less than 30 hours a week to the work of the Department.

Applications and testimonials should be submitted by March 14th.

Further particulars may be obtained from the undersigned.

E. W. MORRIS, House Governor.

The Middlesex Hospital, W.1.

A vacancy for a SURGEON to the Hospital is hereby declared.

A vacancy for an ASSISTANT SURGEON to the Hospital will also occur, and applications for this latter office are invited, to be sent to the undersigned before noon on Monday, March 17th next, accompanied by diplomas and testimonials.

Candidates must be Fellows (or have passed the qualifying examination for Fellowship) of the Royal College of Surgeons of England.

By Order of the Board,
S. R. C. PLIMSOLL,
Feb. 28th, 1930. Secretary-Supt.

County Mental Hospital,
PRESTWICH, near MANCHESTER.

ASSISTANT MEDICAL OFFICER required. Commencing salary £500 per annum, rising to £600 by yearly increments of £25, plus £50 per annum on obtaining the D.P.M., less charges for board, furnished apartments, attendance, and laundry, valued at £150 per annum if received in full. Further increases according to promotion.

Candidates must be unmarried and registered under the Medical Act. The appointment is subject to 3 per cent. deduction from salary under the Asylums Officers Superannuation Act, 1909. Apply, stating age and full particulars, to the Medical Superintendent.

Birmingham Union.
ERDINGTON HOUSE.

RESIDENT ASSISTANT MEDICAL OFFICER (Female).

Applications are invited from fully qualified Medical Practitioners for the above appointment at the Erdington House. The Institution accommodates 1,800 inmates, of whom aproximately 800 are mental patients of varying types and 250 are sick, the remainder being aged and infirm, ordinary House cases, etc. Parts of the Institution are certified under the provisions of the Mental Deficiency Acts, 1913 to 1927.

The person appointed will be required to assist in the general medical work of the Institution and to undertake such other duties as may be assigned to her by authority, and, should occasion arise, to assist at other Institutions.

The minimum and maximum of the scale of salary attached to the appointment are £250 and £350 per annum respectively, and the salar[illegible] late will be fixed with[illegible] to qualifications and [illegible], full residential emoluments (rations, apartments, laundry, and attendance) will be provided. A percentage deduction will be made from the salary and value of emoluments for superannuation purposes, and for this purpose the emoluments are valued at £200 per annum.

Applications, stating age, experience, and qualifications, accompanied by copies of recent testimonials, should be forwarded so as to reach me not later than March 10th.

Canvassing, directly or indirectly, will disqualify.

Union Offices, Edmund Street, Birmingham. C. P. BEECH, Clerk to the Guardians.
February 21st, 1930.

The Hospital for Sick Children,
Great Ormond Street, London, W.C.1.

A HOUSE SURGEON and a HOUSE PHYSICIAN are required on April 4th and 14th respectively.

Gentlemen are invited to send in their applications, addressed to the Secretary, before 12 o'clock on Monday, March 3rd, with copies of not more than three testimonials given specially for the purpose, and also evidence of their having held a responsible Hospital appointment.

The appointments are made for six months. Salaries at the rate of £100 per annum, laundry allowance £5, board and residence in the Hospital.

Candidates must be unmarried and possess a legal qualification to practise.

All candidates must be in attendance to appear before the Joint Committee, if required, at their Meeting on Wednesday, March 5th, at 4.45 p.m. precisely.

Forms of application and copies of the rules may be obtained from the Secretary.

By Order of the Board of Management,
JAMES McKAY,
February, 1930. Secretary.

18. NEAR LIVERPOOL.—Mainly better working-class PRACTICE, producing about £700 p.a., including panel of 854. Fees 2/6 to 5. Mid. 3 to 5 gns.; about 20 cases yearly. Suitable house available on rental. Premium £1,000.
19. LIVERPOOL.—Middle and working-class PRACTICE. Receipts for immediate past twelve months £1,247, including panel of 602 Fees from 2/6. Suitable house, with 2 reception, 4 bedrooms, etc Large garden. Price for leasehold £1,550, of which £1,300 could remain on mortgage. Premium £1,550.
20. LONDON, S.W.—Old-established middle-class PRACTICE, producing over £1,000 p.a., including small panel of 320. Fees 2/6 to 7/6. Mid. lately refused. Good corner house, with ample accommodation. Rent on lease £115 p.a. Premium 1½ years' purchase.
21. SOUTH COAST.—FAVOURITE HEALTH RESORT.—Old-established mixed-class PRACTICE, producing about £1,000 p.a. Small panel of 223. Fees from 2/6. Suitable house, with 3 reception, 5 bedrooms, etc. Large garden. Price for leasehold £1,400, £1,250 on mortgage. Premium £1,200.
22. YORKS.—(North Riding).—Country PRACTICE in beautiful district. Average income over £750, including panel of about 350. Fees 3/6 to 21/-, medicine extra. Nearest opponent 4 miles. Suitable house with 2 reception, 4 bedrooms, etc., and garden of 1 acre. Rent on lease £30 p.a. Prem. 1½ years' purchase, part by instalments.
23. MANCHESTER DISTRICT. — Old-established middle and working-class PRACTICE, worth last year about £700, including panel of 590, and capable of increase. Expenses small. Well-situated house, with 6 rooms in addition to professional rooms. Large garden. Price, freehold, £850. Moderate premium accepted.
24. KENT.—Old-established Country PRACTICE, in favourite locality, and within 5 miles of the coast. Income for past 12 months £1,185, and increasing. Visits 5/- to 21/-. Panel of about 320. Appts. worth about £50 p.a. Convenient house, with ample accommodation. Nice garden. Price for freehold £1 800. Premium 1½ years purchase.
25. YORKS.—PROSPEROUS LARGE TOWN.—Well-established compact PRACTICE, averaging nearly £1,600 p.a., including panel of 1,400. Fees 3/- upwards. Not much midwifery. Low expenses. Very well situated double-fronted house, 2 reception, 4 bedrooms, etc and good professional accommodation. Garden. Price for freehold £1,500 (£1,000 on mortgage). Premium 1½ years' purchase.
26. YORKS.—LARGE TOWN.—Old-established mainly working-class PRACTICE, producing over £1,200 p.a., including panel of over 1,400. Fees 2/6 to 5/-. Well-situated house, with good garden. Price £1,500. Premium £1,200.
27. LONDON, S.W.—A HALF SHARE, with succession in about 2 years, is offered after preliminary assistantship in a good mixed-class non-panel Practice, producing last year over £2,500 Fees 5/- upwards Not much midwifery. Suitable flat or rooms available. Premium 2 years' purchase.
28. YORKS.—LARGE TOWN.—Very old-established middle and working-class PRACTICE, offering exceptional scope for increase. Income for last year £1,500. Panel of over 1,700. Visits 4/6 to 5 Conveniently situated house, with 2 reception, 4 bedrooms, etc Rent on lease £56 p.a. Premium £2,250. Ill health reason for sale.
29. SOUTH AFRICA.—HEALTH RESORT (Inland Spa).—Old-established increasing PRACTICE (held over 20 years) on a main line of rail and in a healthy pleasant township much frequented by visitors in the Season. Cash receipts average over £1,750 p.a., including several appts. One opponent. Price for house £1 250, to include furniture, instruments, and motor car (or final cost £2,000), and for goodwill £1,250, part by instalments Efficient introduction. A knowledge of Hydrology would be a big asset.
30. NEAR WORCESTER.—Old-established Country PRACTICE, averaging over £1,000 p.a., including panel of about 600 Fees 2/6 to 10/6 Good house, with ample accommodation Rent on lease £85 p.a. Premium £1,350, £1,000 down, balance easy instalments.
31. SOMERSET.—Near Hospital Town, in very pleasant residential district, an old-established unopposed Country PRACTICE averaging over £900 p.a., including panel producing about £400 p.a., with mileage and appts. Visits 3/6 to 21 Railway station in place. Nice house (5 bedrooms, dressing and bathrooms, etc., garden). Price, freehold, £1,250, part on mortgage. Prem. £1,250, to include drugs, etc.
32. SOUTH-WEST OF ENGLAND.—POPULAR COAST TOWN.—A one-third share in an old-established PRACTICE, having good surgical scope. Gross cash receipts average £4,200. Panel of 1,800. Suitable house available, on rental. Premium £2,250.

Full Schedule of Terms and Conditions will be forwarded on application.

When the Colon Bacilli Revolt

WHEN the normally non-pathogenic colon bacilli rebel under the influence of foreign invaders or because of the putrefaction and toxæmia resulting from constipation and fæcal impaction, the consequences may be grave in the extreme.

The logical treatment is obviously preventive. In all cases of chronic constipation, incipient stasis or fæcal impaction, and in certain forms of intestinal toxæmia, prompt and efficient evacuation, followed by gradual resumption of normal bowel action, will be obtained by the use of AGAROL Brand Compound, *the original agar-agar emulsion.*

A generous trial quantity sent on request

FRANCIS NEWBERY & SONS, LTD.
31-33, BANNER STREET,
LONDON, E.C.1

Prepared by WILLIAM R. WARNER & CO., INC.
Manufacturing Pharmacists Since 1856

Agarol Brand Compound is the *original* mineral Oil — Agar-Agar Emulsion (with Phenolphthalein) and has Perfec pleasant flavouring; free from sugar, alkalies and alcohol; no oil leakage; no griping or pain; no nausea; not habit forming.

Printed and published by the British Medical Association, at their Office, Tavistock Square, in the Parish of St. Pancras, in the County of London.

OF THE MANY PHARMACEUTICAL PRODUCTS OF DISTINCTION THAT WE HAVE INTRODUCED IN THE PAST THIRTY YEARS NONE HAVE MET WITH SUCH INSTANT SUCCESS AS OUR

ELIXIR FORMASAL

AND.

TAB. ARTHRITONE

IN THE TREATMENT OF ALL RHEUMATIC CONDITIONS

ELIXIR FORMASAL and TAB ARTHRITONE H.H.&CO.

There is abundant testimony of the intrinsic value of the combined treatment in difficult cases which have resisted all other forms of medication

"I AM GLAD TO BE ABLE TO REPORT REMARKABLE PROGRESS IN THE CASES OF RHEUMATOID ARTHRITIS TREATED WITH FORMASAL AND ARTHRITONE: IN MY OPINION THERE IS NO REMEDIAL AGENT WHICH GIVES SUCH RAPID AND SATISFACTORY RESULTS."

MANCHESTER

Intensifying the Action of Physiotherapy

In the treatment of

SINUSITIS,
ERYSIPELAS,
BRONCHITIS,
OTITIS MEDIA,
CHOLECYSTITIS,

and many other conditions in which the application of heat, either of radiant energy from luminous sources, or of diathermy, is indicated, the use of an adjuvant to prolong the effect of these procedures is especially valuable.

Antiphlogistine

is an excellent adjuvant to Physiotherapy.

It forms a warm, impermeable and protective covering over the affected part, which is particularly grateful to the patient.

More than thirty-five years of successful application have confirmed the value of Antiphlogistine in conditions where congestion and inflammation are present.

The Issue of the BRITISH MEDICAL JOURNAL is this week 38,500 copies.

Just Issued

CAMPBELL'S Orthopædic Surgery

Just Issued

There is a freshness, a brilliancy, a *usefulness* about the material in this book which set it at once apart from all other books on orthopædics.

Dr. Campbell robs orthopædic surgery of many of its traditional difficulties. Moreover, he has included in his presentation of the subject Fractures and Dislocations, because these enter so frequently into the practice of the general physician as well as the surgeon and orthopædist.

The diagnosis of orthopædic conditions receives unusual consideration because Dr. Campbell knows that the prevention and correction of deformity require first a thorough understanding of the affections which produce them. A special chapter is given over to *orthopædic examination*, outlining a logical and effective system of examining each member or part.

Treatment is presented with rare clarity and simplicity. This book is not a catalogue of methods but rather a definite detailing of the technique of those methods which Dr. Campbell has himself found of value in orthopædic practice. Moreover, the book is not confined to operative and mechanical methods. On the contrary, every form of treatment which gives promise of result is included—heliotherapy, actinotherapy, marine treatment, exercises, and other non-operative methods.

This new presentation of orthopædics conforms absolutely to modern thought and practice. Its 507 illustrations give it added practical value.

Octavo volume of 705 pages, with 507 illustrations. By WILLIS C. CAMPBELL, M.D., F.A.C.S., Professor of Orthopædic Surgery, University of Tennessee. Cloth, 37s 6d. net.

In Three Volumes

BLUMER'S BEDSIDE DIAGNOSIS

Recently Issued

Edited by GEORGE BLUMER, M.D., David P. Smith Clinical Professor of Medicine, Yale University Medical School. Three octavo volumes, totalling 2,820 pages, with 590 illustrations. Per set, Cloth, £6 15s. net. Index volume free.

"... the book is well bound, the print is excellent, and the illustrations carefully chosen and well reproduced. Not only is each volume indexed but a separately bound index to the whole three volumes is provided, so that fruitless searching in the wrong volume can be avoided. The physician will find it hard to get a finer book."—THE LANCET.

New (3rd) Edition

NEOPLASTIC DISEASES

New (3rd) Edition

By JAMES EWING, Sc.D., M.D., Professor of Pathology, Cornell University Medical School. Octavo of 1,127 pages, with 546 illustrations. Cloth, 63s. net.

"It would be strange to come across any pathological laboratory where this book did not show the signs of frequent consultation. To the surgeon it is a necessity if he would seek to be more than a mere operator. The specialist and the practitioner will find it a mine of useful information."—BRITISH MEDICAL JOURNAL.

Recently Issued

EXAMINATION OF PATIENTS

New (2nd) Edition

By NELLIS B. FOSTER, M.D., Associate Professor of Medicine, Cornell University College of Medicine. Octavo of 592 pages, with 83 Illustrations, a number in colours. Cloth, 21s. net.

"Dr. Foster here records his routine in the examination of patients, and the precision of his writing, the thoroughness of his method, and his critical but sympathetic attitude to recent advances make his book a most valuable one to all those engaged in general practice."—THE LANCET.

A New Work

GONORRHŒA IN THE MALE

Recently Issued

By P. S. PELOUZE, M.D., Associate in Urology and Assistant Genito-Urinary Surgeon, University of Pennsylvania. Octavo of 351 pages, illustrated. Cloth, 24s. net.

"The keynote of this book is simplicity—simplicity in exposition and simplicity in treatment. ... Dr. Pelouze's book should be read by every practitioner who intends to treat gonorrhœa."—BRITISH MEDICAL JOURNAL.

W. B. SAUNDERS COMPANY Ltd. 9, Henrietta Street, LONDON, W.C.2

PATERSON and FOREST SMITH

MODERN METHODS OF FEEDING IN INFANCY AND CHILDHOOD

Second Edition Revised. *7/6 net.*

THE LANCET.—"The first edition of this volume appeared in 1926 and has well established itself as one of the most useful and practical of the shorter books on this subject."

BRITISH MEDICAL JOURNAL.—"The general practitioner confronted with feeding problems will find in this work the practical information he requires presented in a clear and dogmatic manner."

NURSING MIRROR.—"The collaboration of two such authors . . . assures us beforehand of the excellence of this book. The authors modestly describe it as a 'small monograph,' yet it constitutes a very complete guide in all the difficult details of dieting a delicate infant."

NURSING TIMES.—"This monograph deserves high praise. To those who have the responsible work of teaching nurses and midwives the book is to be warmly commended."

PRESCRIBER.—"This volume is the latest word on the subject of infant feeding."

CONSTABLE & Co LTD
10 & 12 ORANGE ST LONDON W.C.2

THE
EXTRA PHARMACOPŒIA
By W. HARRISON MARTINDALE, Ph.D.

Nineteenth Edition.

Vol. I, 27/6 net; postage 6d.
Vol. II, 22,6 net; postage 4d.
Complete Work (2 Volumes) 50/- net, post free.

In Two Volumes.

Vol. I (1928) deals chiefly with Treatment, giving the important issues as to CLINICAL USE of all modern CHEMICALS and DRUGS, characters, dosage, methods of prescribing, etc.
Vol. II (1929) COMPLETES THE SET. It is concerned with INVESTIGATIONS, EXPERIMENTAL RESEARCH, DIAGNOSIS, and a large amount of new matter in medicine and allied sciences.

BRIT. MED. JOURN., Nov. 2nd, 1929, says: "*Has a well-established reputation as a most useful and convenient work of reference.*"
LANCET, Nov. 2nd, 1929, says: "*A clear and authoritative publication of the highest value.*"

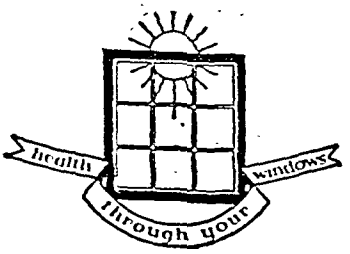
HEALTHY HOUSES DESIGNED IN THE CONSULTING ROOM



Thousands of homes are influenced by what their owners learn in the doctor's consulting room. The doctor is the architect of health. His recommendation can transform a healthless room into a healthy room; and he effects such changes every time he suggests the use of "Vita" Glass to his patients.

"Vita" Glass is the only British window glass that admits the ultra-violet rays which ordinary glass shuts out. Its power of admitting these rays is permanent, and "Vita" Glass windows are effective health inlets all the year round, whether they face north, south, east or west.

"Fit 'Vita' Glass" is not a costly suggestion to-day. For a window of average size can be fitted with "Vita" Glass for 38/-, plus the cost of fixing.

Further information about "Vita" Glass will be sent to any Medical man who is interested. Write to: 9, Crown Glass Works, St. Helens, Lancs. London Office: Aldwych House, W.C.2.

"Vita" Glass is obtainable from local Glass Merchants, Plumbers, Glaziers or Builders.

"Vita" is the registered Trade Mark of Pilkington Brothers, Limited, St. Helens.

V.203

Comfortable Post-Operative Support for Your Surgical Patient.

Danger of nephroptosis following the removal of a large abdominal tumour probably indicates careful support for your patient.

Ruptured appendix with drainage places such a heavy tax upon the vitality of your patient that you may wish to recommend the wearing of an abdominal support during convalescence.

Or a sensitive scar after a gall-bladder operation may need the protection of a special support, with laparotomy pad.

After any abdominal operation, a Spencer supporting corset or abdominal belt gives your patient great comfort and sense of security. The support can be made of light as well as of firm material. It can be soft and pliable for comfort. But because each Spencer support is especially designed for the person who will wear it, it will give the support that you want your patient to have.

This is a Supporting Corset with the front opened to show the inner belt which supports the abdomen. Adjustment of the belt is made from the outside of the support.

The Spencer Corsetière will call at your surgery or at your patient's home to take the necessary measurements, and to get your special instructions about the case in hand. Spencer corsets and supports are never sold in stores.

If there is no Corsetière in your vicinity write direct to us.

We issue booklets on the use of Spencer Supports for the relief of sacro-iliac strain, hernia, enteroptosis, movable kidney, and for maternity and post-partum wear. We will gladly send you any of them in which you are interested.

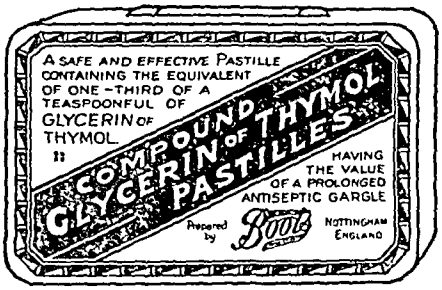
Irritable Bowel



Nujol is of great assistance in the treatment of chronic irritable bowel. Unlike cathartics, whose action is stimulating to the muscles or irritating to the lining of the intestines causing excessive secretion of mucus, Nujol acts merely as a gentle lubricant and solvent of impacted fecal matter. Though it absorbs intestinal toxins to a high degree, it cannot, itself, be absorbed. Consequently, toxemia is prevented, peristalsis is at a natural rate, and the stool is normal and properly formed.

a new & genuine antiseptic pastille

COMPOUND

GLYCERIN OF THYMOL PASTILLES

The increasing use of Compound Glycerin of Thymol as an antiseptic and anti-catarrhal wash has suggested to us the introduction of this Pastille. **Each Pastille contains the equivalent of 20 minims of Glycerinum Thymol Co. B.P.C., fortified by the addition of a powerful new antiseptic, Amyl-Meta-Cresol, discovered in the Research Laboratories of Boots Pure Drug Co. Ltd.**

This antiseptic has a R.W. co-efficient of 250, and the equivalent of 2½ grains of pure Phenol has been added to each pastille.

The Pastilles have a refreshing flavour and will be found entirely pleasant in use.

BOOTS PURE DRUG CO. LTD., NOTTINGHAM.

CHOSEN BY THE MEDICAL PROFESSION FOR NEARLY A CENTURY . . . FOR THEIR POWER TO STIMULATE AND RESTORE APPETITE

BY APPOINTMENT

Made by an exclusive process, first discovered by Mr. Brand nearly a century ago, Brand's Essences are of inestimable value to the medical profession.

During convalescent periods and in cases of extreme exhaustion. Brand's Essence, administered in small quantities, has a gentle but stimulating effect on the gastric juices. Brand's Essences excite appetite and help in overcoming that reluctance to eat so apparent after critical illnesses.

These Essences are made entirely from freshly killed British meats under the most hygienic conditions. They are perfectly pure — and possess the maximum amount of nourishment. No gelatine, artificial colouring or preservatives are added. They can be swallowed without effort, and the digestive organs absorb them without strain.

There are three kinds of Brand's Essence to choose from — Beef, Chicken and Mutton. They can all be obtained at chemists and stores throughout the world in small and large-sized tins and glasses. Brand & Company Limited, Mayfair Works, South Lambeth Road, London, S.W.8.

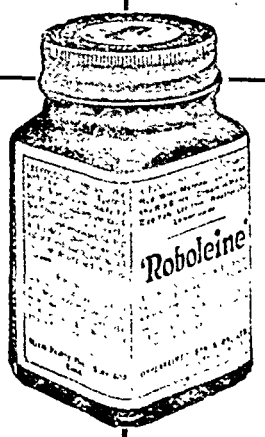
The Urinary Antiseptic with an Analgesic Action

CAPROKOL

For the prompt relief of pain, fever, frequency of micturition and other unpleasant symptoms associated with diseases of the urinary system, Caprokol therapy has proved remarkably effective

Caprokol is an analgesic as well as an antiseptic; hence it exerts a soothing effect upon the mucosa during the process of sterilisation of the urinary tract.



Persistent administration of Caprokol in cases of cystitis, pyelitis, urethritis and allied disorders, leads, in most instances, to complete recovery.

FORMULA

Each tablet contains in lipoid soluble form:

Iron	6 mg.
Copper	0.6 mg.
Manganese	0·5 mg
Zinc	0.4 mg.
Nickel	0.04 mg
Cobalt	0.04 mg.
with the addition of	
Sodium Germanate	0.05 mg.

Unique stability of Lysolat in Salt solutions

Antiseptics have so often to be used in the presence of organic matter that the effect upon them of various salts (the chlorides in particular) is a vital factor in their germicidal efficacy.

The illustration shows a 10 per cent. solution of various lysols and other common or proprietary antiseptics, in water to which 3 per cent of sodium chloride has been added. It will be seen that No. 1 (Lysolat) alone preserves a perfect emulsion, the others having been broken up and their antiseptic qualities destroyed.

Medical Men will realise the significance of this test. It is well known that in the presence of certain emulsifying agents, free bacteria exert a buffering action upon clots of organic matter, breaking them up and liberating the bacteria within. The presence of a chloride greatly diminishes this disintegrating action and destroys the emulsion. Where the emulsion carries an antiseptic or disinfectant the latter is separated and rendered ineffective.

Experiment has proved that the cresol isomers tend to correct the depressing effect of chlorides upon the bacteria, but they can obviously prove germicidally efficient only in a state of perfect emulsification. Lysolats are composed of the most active and powerful of the cresols emulsified by an emulsifying agent of unique stability.

Lysolats
PATENT SEALED (LYSOL TABLETS)

Lysol in one pint of boiling water to make 1, 2, 3, 4, 5 and 6 per cent. solutions of Lysol.

Builds up in underweight conditions and provides a perfectly balanced, highly nutritive diet for growing children

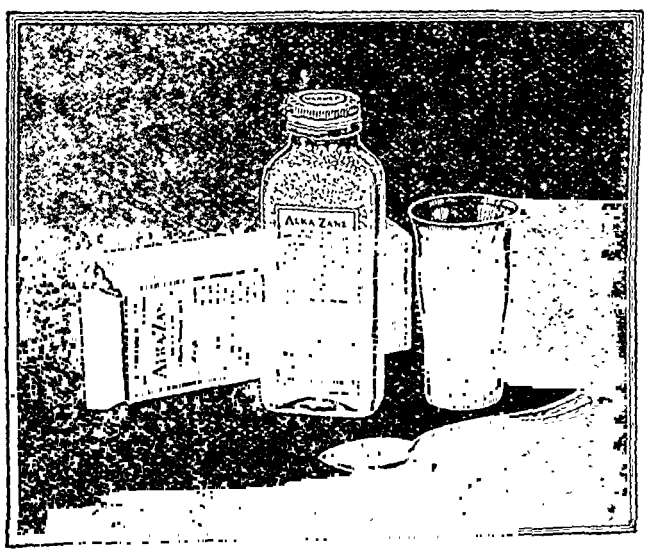
TO the problem of the "underweight" child Horlick's Malted Milk provides a convenient solution.

For many years it has been successfully used by the medical and nursing professions for fast-growing children, for invalids, for expectant and nursing mothers — in all cases where it is particularly important to sustain strength and replenish natural energy quickly.

Excellent results obtained by adding Horlick's to the diet of growing children have been strikingly recorded in many thousands of letters written by parents and members of the medical profession.

Made from fresh, full-cream cows' milk, selected wheat and malted barley, Horlick's Malted Milk constitutes a perfectly balanced food — containing fat, proteids, and soluble carbohydrates in correct nutritive ratio.

The vitamins of its constituents are unimpaired by the Horlick process.



Horlick's contains neither cane sugar nor unaltered starch, but presents in proper proportions a sufficiency of valuable malt sugars, for which children have a greater toleration. Moreover, Horlick's is partially pre-digested during manufacture, thereby assuring perfect assimilation.

In addition to its important body-building qualities, Horlick's has the advantage of being an extremely palatable beverage. Most children like the natural flavour of malt and will drink Horlick's with pleasure. And it is now obtainable also in a new Chocolate Flavoured form — identical in constituents with the original Horlick's, but with fine chocolate added.

Horlick's Malted Milk (both forms) is obtainable everywhere in sealed glass bottles, at 2/-, 3/6, 8/6 and 15/-. Also in tablets.

Further details and supplies for tests may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

Immunity and Alkalinity

A pleasant, effervescent granular preparation composed of carefully selected salts of Sodium, Potassium, Calcium and Magnesium in physiologically correct proportions.

appear, in the opinion of competent observers, to be in close relationship. At least it is certain that alkalinity is lowered in all infectious diseases, and that excess production or defective elimination of acid products lead to a number of metabolic disturbances.

To correct these conditions, present particularly in gastric and intestinal disorders, rheumatism, gout, and certain cutaneous affections, and to prevent their occurrence as a sequel to undue reduction of the buffer substances of the blood, prescribe

MANGANESE BUTYRATE
B. D. H.

in the Treatment of Acute Conditions

In the treatment of a variety of acute conditions Manganese Butyrate B.D.H. has proved to be a drug of exceptional value. For example, in gonorrhœa, when the disease has taken hold thoroughly, and acute conditions occur, intramuscular injections of Manganese Butyrate B.D.H. will often effect a complete dissipation of the trouble with suprising rapidity.

The chief value of Manganese Butyrate B.D.H. seems to lie in its power to fortify the host against staphylococcic and streptococcic infections rather than against gonococcic infection, and herein appears to be the explanation of its remarkable success in furunculosis, carbuncles, erysipelas (including the form following vaccination), whitlows, etc.

Manganese Butyrate B.D.H. is issued in ampoules and in rubber-capped vaccine bottles containing a solution ready for intramuscular injection.

Toxæmias of Pregnancy

Biochemistry and Endocrinology prove beyond dispute that pregnant women are weakened in their defences against general disease and septic invasions.

A lowered resistance, often accentuated by the modified shock of parturition, makes PUERPERAL SEPSIS only too simple a matter in many cases, in spite of faultless obstetric technique.

The toxæmias of pregnancy have been investigated and illuminated extensively in the past ten years by the patient research of many brilliant observers, who are all emphatic in representing the importance of intestinal toxæmia in the puerperal picture. Their conclusions point to the necessity of providing

A Safe Intestinal Bactericide

to promote the well being of mother and child by limitation of putrefactive changes in the bowel during the later months of gestation and until the post-puerperal period is passed.

Such a product is now available in the form of Dimol, the effect of which can be readily estimated by the gradual disappearance from the urine of the toxins—tyramine, indican, skatol, etc.

The Obstetrician who wishes to push his investigations into the fascinating subject of the influence of intestinal toxæmia upon intra-uterine life is now furnished with a powerful weapon of research.

The efficiency of Dimol in the treatment of many other intestinal conditions of bacterial origin is conclusively proved in the interesting clinical reports which, together with a brochure dealing with the pathological significance of the intestinal toxæmias, will be sent to any physician on application to the

Dimol Laboratories, 40, Ludgate Hill, London, E.C.4.

Kalzana promotes Calcium Retention

The value of Kalzana tablets lies in their combination of calcium lactate and sodium lactate. In the body the sodium lactate becomes converted into sodium carbonate and imparts the requisite alkalescence to the blood which is necessary to ensure calcium retention. The reports of eminent physicians show that Kalzana possesses all the advantages which one may expect from a calcium preparation.

"The Practitioner" says:

"Kalzana acts efficiently in promoting the growth of strong bones and healthy teeth, in protecting the expectant and nursing mother against a dangerous loss of calcium . . . . particularly because Kalzana promotes calcium retention."

Dispensed by Chemists in air-tight packets containing 50 and 100 tablets.

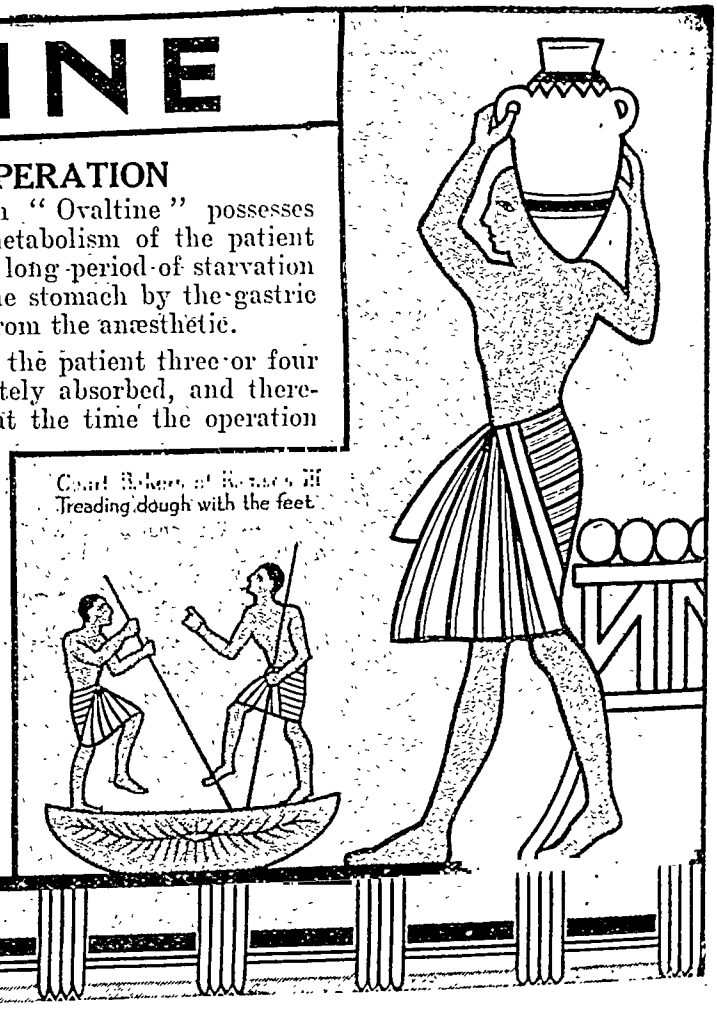
OVALTINE

BEFORE AND AFTER OPERATION

As a diet preparatory to surgical operation "Ovaltine" possesses unique advantages. It tends to keep the metabolism of the patient as nearly normal as possible. It also avoids a long period of starvation prior to operation, consequent irritation of the stomach by the gastric flow, and predisposition to greater irritation from the anæsthetic.



"Ovaltine" provides a means of nourishing the patient three or four hours before operation. It is almost completely absorbed, and therefore the stomach and intestines are empty at the time the operation is conducted.

"Ovaltine" lessens the predisposition to shock and counteracts the tendency to acidosis common after chloroform and ether anæsthetics.

In the usual processes of post-operative feeding by easy stages, from sips of water to the regular diet, "Ovaltine," by reason of its delightful palatability, ready digestibility, and high nourishing power, is ideally adapted.

A liberal supply for clinical trial sent free on request.

Local Anæsthesia in Surgical Practice

REDUCTION OF DISLOCATION.

TYPICAL CASE.

K. M. J., aged 50 years.

Diagnosis: Subluxation of the left shoulder-joint.

Operation: Reduction by closed methods.

Anæsthesia: Brachial block, using 5 c.c. of a 1 per cent. solution. There was a numbness of the hand seven minutes after the injection of the brachial plexus. Complete relaxation was obtained and reduction was accomplished by manipulation. In this case induction of anæsthesia and reduction of the dislocation required but ten minutes.

—EXTRACT from PRACTICAL LOCAL ANÆSTHESIA (Farr).

(Full technique of this and one hundred other operations under Local Anæsthesia will be found in the above work, published by Henry Kimpton, 263, High Holborn, London, W.C.1.)

THE SAFEST LOCAL ANÆSTHETIC.

Vita-Weat—the perfect "staff of life"

Analysis and tests of Vita-Weat, the British whole-wheat crispbread, show that it possesses in a marked degree the six essential constituents—carbohydrates, fat, proteins, mineral salts, water, *and the essential vitamins.*

100% Whole Wheat.

Being made from the whole wheat berry, from which nothing has been removed in manufacture, Vita-Weat yields the highest natural percentage of cereal proteins, and by the process of manufacture the starch present is rendered easily available for the solvent action of the amylolytic ferments of the human digestive juices.

Further, Vita-Weat is specially valuable as a natural stimulant to peristaltic action of the intestines, and when forming a suitable proportion of the daily diet effectively counteracts constipation.

Vitamins A, D, and B.

The dry condition of Vita-Weat is of distinct advantage in cases of flatulence in which moist foods are largely contra-indicated, and the crisp character of the sections also helps to reduce the intake of soft foods, giving the teeth and masticating muscles something to do and ensuring complete and thorough salivation of the food bolus.

Vita-Weat crispbread presents the whole wheat berry in a concentrated, attractive and digestible form with the Vitamins A, D & B in an active condition, and it forms a valuable addition to rational diet, presenting a dainty and advantageous alternative to soft wholemeal or white bread.

Dried Milk for Safety

At————deaths from diarrhoea and enteritis fell from 105 in 1923 to 67 in 1924, but rose to 109 in 1926. There was a fall in 1927 to 61, and a further fall in 1928 to 56. Professor ————M.O.H., writes: "Once more the relationship between these diseases and the sub-soil (four-foot) temperature, which used to be so constant, failed to re-appear. Among the most important factors in bringing about this amazing decline in mortality from these causes, I think we must place the wide substitution of dried milk for so-called fresh but highly contaminated milk————" Dr.————adds that until the methods of the farmers and others concerned in the milk industry have been revolutionised, and consumers have been provided with facilities for storage and education in the handling of milk, he is definitely of the opinion that liquid milk should be banished from the dietary of infants.

"Medical Officer,"
Jan. 4th, 1930.

This resumé shows clearly the advance made in medical opinion during the last few years. Figures such as these show conclusively that raw cows' milk—"Nature's food for the calf"—is unsafe and unsuitable for the human infant. Discrimination in the choice of a dried milk food is, however, essential.

The makers of Cow & Gate have for over a quarter of a century endeavoured by every means known to science to produce each year a better product, and in the light of this experience they postulate without fear of contradiction that there is a great gulf fixed between ordinary commercial dried milk and that specially prepared for infant feeding.

Some babies cannot digest full cream milk; they should be put on Cow & Gate Half Cream. (BLUE TIN)

The confidence of the MEDICAL PROFESSION.

Benger's Food has gained its unique position not by extravagant or sensational advertising but by the constant recommendation of medical men and women. To-day it is universally used not only at home but throughout the world. Few foods have so enjoyed the approbation of the Medical Profession for over 40 years.

Benger's Food differs from all other foods in that it is especially prepared to adjust fresh cows' milk or cows' milk and water so as to suit the condition of any patient. While it is largely used as a routine treatment in all cases of disordered digestion the following comments, which have been recently made by Doctors, indicate some specific uses to which Benger's Food has been put.

DYSPEPSIA.

"routine food in all cases of dyspepsia and disordered digestion."

"used for invalids and all gastric cases."

INFLUENZA.

"very largely used for Influenza in all its forms."

CANCER.

"invaluable for cancer of the throat."

"cancer of the stomach—doing well on Benger's Food."

THE AGED.

"very beneficial for man of greatly advanced years."

"invariably used for invalids and aged persons."

A Physician's Sample will be sent post free to any member of the Medical Profession making application to the Proprietors—

STOMACH TISSUE
in
PERNICIOUS ANÆMIA

Recent publications in English and American literature indicate that hog's stomach is highly effective in the treatment of Pernicious Anæmia. This was especially noted in cases which did not respond satisfactorily to liver extract and in the treatment of achlorhydria, glossitis and paræsthesia.

In this connexion we have introduced

GASTREX

a carefully prepared, desiccated and defatted form of fresh hog's stomach tissue, presented as a finely powdered and pleasantly flavoured product. Supplies are now available for distribution to the Medical Profession, to whom full particulars will be sent on request.

The Original and Standard Emulsion of Petroleum

Angier's Emulsion

is made with petroleum specially purified for internal use. It is the original petroleum emulsion—the result of many years of careful research and experiment.

Influenza and Sequelæ.

The unique soothing properties of Angier's Emulsion and its favourable influence upon assimilation and nutrition make it eminently useful both during and after influenza. It has proved most efficacious in relieving the catarrhal symptoms, whether tonsillar, bronchial, or intestinal; also in combating the nervous depression and debility. After the attack, or when the patient's nutrition and vitality are at the lowest ebb, try the continued use of Angier's Emulsion for convincing proof of its effects as a tonic and restorative.

Bronchitis, Sub-Acute and Chronic.

There is a vast amount of evidence of the most positive character proving the efficacy of Angier's Emulsion in sub-acute and chronic bronchitis. It not only relieves the cough, facilitates expectoration, and allays inflammation, but it likewise improves nutrition and effectually overcomes the constitutional debility so frequently associated with these cases.

In Gastro-intestinal Disorders

of a catarrhal, fermentative, ulcerative, or tubercular nature, Angier's Emulsion is particularly useful. It exercises sedative, demulcent, lubricant effects throughout the entire intestinal canal, and it restores tone to all the digestive functions. Moreover, it offers the very best vehicle for the administration of astringents and antiseptics (bismuth, salol, &c.) The Emulsion may be administered undiluted or in any desired vehicle.

SCULPTURED HEADS FOUND IN SOUTH-WESTERN ARABIA.—Sculptured heads and sometimes statues were used by these early Arabs for sepulchral purposes. They have but trifling artistic value and they do not help to settle the ethnological question. As to the origin of the ancient Arabs, ethnologists are not unanimous. They appear to agree that both Arabs proper and Bedouins are of Semitic stock in a wide sense. Many believe that Arabia is the original home of the Semites. Arab and Jewish tradition derive the people of the Peninsula from two stocks—those of the north called "naturalised Arabs," from that of Ishmael; those of the south, the "pure Arabs," from Joktan fourth in descent from Shem. The significance of early Arabia for the later world may be gathered from these words of a great student of Eastern questions: "Islam was born in the desert, with Arab Sabæanism for its mother, Judaism for its father; its foster-nurse was Eastern Christianity."

DIET AND CONSTIPATION.

THOUGH in all cases of intestinal atony the diet should be carefully considered, it has recently been pointed out by a distinguished physician attached to our largest hospital that "*in spite of the general belief, not very much can be done by diet in the treatment of constipation; and the patient's mind should be disabused of the idea that there is any particular harm in taking a regular aperient, provided it is of the right kind.*"

It can confidently be claimed that Eno's "Fruit Salt" comes within this category, for it is an aperient which acts solely by retaining water in the bowel—as a result of its increased osmotic density—thus maintaining bulk and adequate pressure, and so promoting peristalsis.

In contradistinction to most aperients, Eno's "Fruit Salt" has no irritant or chemical effect on the mucous membrane—and accordingly produces no nausea or discomfort.

"The Doctor's Emergency Reminder."

The Proprietors of Eno's "Fruit Salt" will deem it a privilege to send to any member of the Medical Profession a copy of the latest addition to their series of "Medical Reminders"—with or without a bottle of their preparation (Handy or Household size as required). "THE DOCTOR'S EMERGENCY REMINDER" summarises briefly a few points in connection with the treatment of poisoning and various other emergency cases. It is bound in black morocco limp to conform to the style of the previous publications in this series.

Remarks
ON
INDIGESTION FROM A SURGEON'S STANDPOINT.*

BY
H. W. CARSON, F.R.C.S.,
SENIOR SURGEON, PRINCE OF WALES'S GENERAL HOSPITAL; CONSULTING SURGEON, HERTFORD COUNTY HOSPITAL.

To discuss indigestion among the common complaints is obviously correct, because it is probable that nearly everyone from time to time experiences sensations due to temporary upsets in the complicated co-ordination of gastro-intestinal physiology; but the fact that some of these upsets are due to surgical disorders, and may necessitate an operation of more or less severity, raises them above the plane of minor ailments, though they may still be common complaints.

The title of this address suggests that indigestion may be divided into strict categories—that there is a type with which the surgeon must deal, a type for the physician, and doubtless another for the gynaecologist. But is that really so? I would rather say that the standpoint—that is, the point from which we view the patient—is the same for all medical men, and that the time has gone by when the surgeon was merely a craftsman obeying the order of his superior, the physician. Nowadays we all, whatever our label, insist on making our own diagnosis. We are all equally equipped to investigate conditions, however obscure; we use the same diagnostic tools, and, in most cases, come to the same conclusions. We still differ, though to a constantly diminishing extent, on treatment; but with an increasing appreciation, not so much of the nature of a disorder as of the stage at which it has arrived, we must inevitably reduce the number of those cases where differences still exist. We surgeons can take some credit for insisting on what has well been called the living pathology—that is, for exposing to the eye and permitting the minute examination of diseased organs at an early stage—a study more fruitful than is an examination, after death, of structures so altered by prolonged disease that the early signs are unrecognizable. I would mention, as an example, how the knowledge that has resulted from the histological examination of the gall-bladder, removed at an early stage of the disease, has led to a correct estimation of the effect that cholecystitis has on the general health, and to a realization of how much more important the *disease* of the gall-bladder is than the *stones* it may happen to lodge. Or, as another example, how a critical examination of displaced viscera has led us to modify the views at first held on visceroptosis. Of course, it may be years before some ingrained beliefs are abandoned—such as, for instance, that hyperchlorhydria is a disease, and that it is due to overwork, or that recurring abdominal pain in children is due to "bilious attacks," or that gall-stones can be cured by medical treatment. But, gradually, knowledge is spreading that surgery has done much to explain the early stages of many abdominal complaints, and that certain abdominal disorders, as far as their treatment is concerned, are purely surgical from the very beginning.

DISORDERS OF THE STOMACH.

When one talks of indigestion, one thinks at once of the stomach, and certain questions arise which require an answer. A. Is the stomach itself diseased, or is it acting in sympathy with some other diseased organ? B. If the stomach is at fault, is it because of some physiological variation or of a pathological change? C. If a pathological change, is that amenable to medical treatment, or must some direct attack be made on it by a surgical operation?

A. We know that a perfectly healthy stomach may be so affected by disease in other viscera that its disordered action may simulate a definite lesion. The best known instances are the dyspepsias in lesions of the appendix and in gall-stones. It is accepted that gastric pain is due to disordered muscular action, and is really an exaggeration of normal sensations, such as hunger, which are associated with hypermotility. The presence of some irritable focus, such as a chronic appendicitis or cholecystitis, excites a hyperperistalsis in the stomach, and pain results. It is for the diagnostician to distinguish between this condition and a similar condition due to a local lesion, for it is obvious that treatment directed to a referred condition must be ineffectual while the causative lesion is still active.

It is interesting to note that appendicitis will more readily excite symptoms of duodenal ulcer in persons of the duodenal diathesis—stalwart, well-developed men, in whom hypermotility and hypersecretion are the rule—and symptoms of gastric ulcer in the hyposthenic type with a narrow chest, poor physique, and a tendency to visceroptosis, in whom gastric motility and secretion are both on a lower plane. Our first duty, then, is to distinguish between actual and referred symptoms, and everything depends on a correct answer to this first question.

B. Investigation has proved that the stomach is very responsive to internal and external stimuli. The flow of gastric juice is excited or inhibited by many causes, some of them physical, others mental, and even the level of the gastric curvature may vary at the call of the emotions, so that the "sinking feeling" has a real physical basis. Too much reliance cannot, then, be placed on decimal variation in gastric acidity, but, if there is a pathological change in the stomach, the investigation of gastric secretion may be of real assistance. We know, too, that a small proportion of healthy and otherwise normal people have no free hydrochloric acid in their gastric secretion, but whether that renders them more liable to develop diseases associated with low gastric acidity—for example, pernicious anaemia or gastric cancer—is not known. We do know that they have a normal appetite and good digestion, in spite of this apparent anomaly. It is very doubtful whether variations in gastric secretion give rise to symptoms, and to distinguish between physiological variations and pathological variations requires other means of investigation, among which the *x*-ray barium meal examination and the chemical examination of the stools have chief place.

C. Having determined that a pathological lesion is present, the question arises as to the prospect of permanent cure, and the choice of methods to ensure it. It is here that the medical view and the surgical view diverge. Until quite recently the disappearance of symptoms was looked upon as evidence of cure, but with more exact methods of examination we know now that, while in practically every patient with gastric or duodenal ulcer confined to bed, and treated on medical lines, all the symptoms will disappear in a few days, the ulcer takes many weeks to heal, and may even remain unhealed. We know also that from time to time the *x* rays will demonstrate the gradual diminution in size and eventual disappearance of really large crater ulcers under medical treatment. The question we have to answer is: What type of ulcer gives a reasonable chance of cure by medical means, and what are the chances of such a cure being permanent? We know that all superficial ulcers of the stomach and duodenum are associated with remission of symptoms, sometimes for long periods, but that there is a tendency to recurrence. It is probable—and I think I have proved it by seeing many of these conditions during abdominal operations—that during a remission the ulcer really heals. Have we any assurance that a superficial ulcer healed under medical treatment will be less likely to recur than one which heals without treatment? There can be no answer to the question until we can collect the after-histories of thousands of contrasted cases. With regard to crater ulcers, the matter is less controversial. Remissions in these cases are less the rule, and these ulcers behave like all other ulcers with a more or less fixed base in their reluctance to heal and their tendency to break down again. In spite of the gratifying progress seen by the *x* rays in some of these cases treated medically, I am convinced that the proportion of recurrences is so high that medical treatment is not ideal for these cases, even if we overlook the fact that these are

* A paper read before the East Herts Division of the British Medical Association on January 2nd, 1930.

essentially the cases in which grave complications occur. Of these complications, perforation has lost much of its terror since early intervention became the rule, but haemorrhage is still a serious sequel, and one that is too often beyond surgical skill. I have at present in my wards a patient who had on two occasions been entered for admission for a duodenal ulcer, and had twice refused the bed owing to remission of symptoms. The ulcer perforated a few days ago, and he has had a hard fight for his life.

Another point bearing on the choice of treatment arises from one's views on the etiology of gastric and duodenal ulcer. The opinion is widely held that these ulcers are not primary, but are secondary to some septic focus elsewhere; and, in their turn, the teeth, the tonsils, the nasal sinuses, the gall-bladder, the appendix, and indeed the whole intestinal tract, have been suspected of being the source of the infection. I have been impressed by this theory, as, in the days when I treated lesser curve ulcers by excision only, I saw many recurrences at the site of excision—a very natural sequel if all I had done was to remove a result and leave the cause behind. I have also seen patients with duodenal ulcer, upon whom I have performed gastro-jejunostomy, fail to obtain relief until the appendix or the gall-bladder has been removed at a subsequent operation. In accordance with this belief, it has long been an accepted line of treatment by physicians and surgeons alike to look for, and, if they are present, deal with all forms of sepsis in the upper respiratory and alimentary tracts as a preliminary to treating the ulcer. But it is impossible by any means other than a laparotomy to obtain a real knowledge of the condition of the gall-bladder or appendix; nor is it possible to get rid of these two common foci of infection by any means except their removal by operation. If, then, there is reason to suspect that an ulcer in the stomach or duodenum is associated with a lesion of the appendix or gall-bladder, a permanent cure can be hoped for only by operation.

LESIONS OF THE APPENDIX.

I need not apologize for taking up your time by discussing the dyspepsia associated with and due to chronic appendicitis. The old controversies as to whether the appendix, crippled by an attack of acute inflammation, could, when apparently quiescent, give rise to symptoms, have all died down, and there is general agreement that an abnormal appendix can give rise to dyspeptic symptoms. Indeed, it is probably a frequent cause of the type of dyspepsia in children commonly labelled "bilious attacks." But the symptoms may be anomalous; they may be indefinite, or they may point to a different organ, and so we undoubtedly see mistakes made in the diagnosis of appendix dyspepsia. Many times has the appendix been removed, and a duodenal ulcer or cholecystitis left undiscovered and untreated. These mistakes do and will occur in spite of all our care; but their number may be reduced by the strictness of our investigation, and perhaps particularly by our realizing that such mistakes are possible.

What symptoms are we to rely on for a diagnosis of chronic appendicitis? Some cases are quite easy. There is a history of characteristic attacks with intermissions during which the patient may, or may not, be free from discomfort. But it is in the cases where there have been no definite attacks that difficulty arises. Indeed, some surgeons maintain that the chronic appendix does not exist unless there have been definite acute attacks. I believe that there is a type of chronic appendicitis, characterized by sclerosis and thickening of the organ with obliteration of the lumen from the tip, which can arise independently of acute attacks of inflammation. This type of appendicitis gives rise to a train of symptoms referred to the stomach and accompanied by some minor local discomfort.

Probably the commonest error is to confuse appendicitis and visceroptosis. We know now that variations in level of the abdominal viscera occur in quite healthy people; but it is not difficult to diagnose pathological visceroptosis. The symptoms are typical; the patient herself is typical. But the question we have to answer correctly is this: "I know this patient has visceroptosis; I know that all her symptoms could be due to that disorder; but can I be certain that the fixed pain she complains of in the right iliac fossa is not due to a coexisting disease of the appendix?" We have all seen scores of cases of visceroptosis in which the removed appendix gives every sign of chronic inflammation. And so the appendix is removed and the patient starts on the long downward path of repeated operations. Two months ago a patient was referred to me who had had eleven operations; last week I saw a woman of 35 who had begun her operative life—if you might so call it—at 18, and had had six more operations since then. Each operation seems to give temporary relief, but is soon followed by what is euphemistically called "adhesions," and another operation is done. There is no doubt that there is real difficulty in excluding disease of the appendix in cases of agreed visceroptosis; but my advice would be that, in spite of an occasional brilliant success from anchoring operations, visceroptosis is not a disorder which is likely to benefit from surgery.

Unfortunately, the barium x-ray examination rarely helps much in the diagnosis of appendicitis. Occasionally it is possible to visualize the appendix and to prove that it is adherent and tender, but, unless the appendix is visualized, no opinion can be given, and we know that many of these atrophic sclerosed appendices are quite free from adhesion. I should sum up the question by saying that local pain, and even tenderness in the appendix area, unaccompanied by "indigestion," must not be accepted as evidence of appendicitis in the absence of a history of acute attacks.

DISEASE OF THE GALL-BLADDER.

Chronic cholecystitis presents an even more difficult problem. I do not refer here to cases complicated by the presence of gall-stones, for many of these give rise to a characteristic train of symptoms which makes diagnosis easy. It is the type where a low-grade streptococcal infection deep to the mucosa leads to gradual thickening and distortion of the gall-bladder, often with adhesions to the neighbouring structures. This pathological condition has been discovered and investigated purely by the efforts of the surgeons, who have been able to see the early changes in the gall-bladder, and, by removing the organ, to examine it histologically and bacteriologically at all stages of the disease. We know that the infection is generally due to a streptococcus; that it is blood-borne; that its seat is deep to the mucosa, which for a long time is unaffected; that it leads to gradual changes in the appearance of the gall-bladder; and that it may have effects on the general health much more widespread than its effect on the digestive apparatus. The healthy gall-bladder is a bright sky blue in colour, a colour which extends down to the cystic duct, which is enclosed in a fatty envelope. When the gall-bladder is diseased, the first change is seen near the cystic duct, where the fatty envelope seems to be spreading towards the fundus. The gall-bladder loses its bright colour, the last to disappear being at the fundus, and at the same time it becomes thickened and contracted until it reaches the stage, so often seen in the post-mortem room, of a yellow, shrunken, distorted organ. With this occurs a local hepatitis, so that the gall-bladder becomes intimately adherent to the liver, instead of being attached to it by a loose areolar bed.

The symptoms are not too clear-cut in the absence of stones, but, in most cases, the patient complains of an almost constant aching and dragging in the right hypochondrium, not referred to the angle of the scapula as frequently as when stones are present. Loss of appetite with flatulent dyspepsia, and a disinclination to take fatty foods, are common—taking food excites the pain, especially if adhesions are present—and sometimes there is definite loss of weight. From time to time mucus may form and lodge in the cystic duct, giving rise to a modified kind of colic. The only clinical sign of any diagnostic value is the occurrence of local tenderness elicited by Murphy's method, but occasionally one finds the liver enlarged.

There are two methods of investigation which may, as technique becomes standardized, lead to a great advance in the diagnosis. The x-ray examination of the gall-

bladder after administration of the dye tetraiodophenolphthalein has already proved its value. The dye may be administered intravenously or by the mouth in capsule. The former method is certain, but has technical difficulties: the latter is less certain, as one is not always sure that the dye is absorbed, but it is easy. In both cases the patients must be carefully prepared. The dye is excreted almost entirely in the bile, and should appear in the healthy gall-bladder four hours after intravenous administration, or twelve hours after oral administration. The shadow, light at first, becomes denser as the bile becomes concentrated, and repeated photographs are taken; a meal rich in fats is then given, and the gall-bladder empties. The patient is without food for at least fifteen hours. *Failure to obtain a shadow* after intravenous administration shows something amiss in the biliary apparatus; after oral administration, it may mean only a failure of absorption, and is a demand for intravenous administration. *Mottling of shadow* suggests calculi, which are often defined very clearly. *Irregularity of contour* suggests adhesions, and *variations in density and time of appearance and disappearance* suggest functional derangement. A wide experience is necessary to assess the value of this last sign.

The other method is one employed and perfected by Dr. Vincent Lyon of Philadelphia, who has demonstrated this method to me on several occasions. It involves the use of a duodenal tube, which is passed through the stomach into the first part of the duodenum; a saturated solution of magnesium sulphate is introduced through the tube, and in a few minutes the contents of the duodenum are withdrawn by suction. The magnesium sulphate relaxes the sphincter of Oddi, and Dr. Lyon maintains that he is able to collect the bile from the common duct, from the gall-bladder, and from the hepatic ducts into separate receptacles, and examine each specimen microscopically, chemically, and bacteriologically. I have seen many results of these experiments, and I am satisfied that from them a great deal can be learned about the condition of the biliary passages.

The treatment of an infected gall-bladder is removal. There is no certainty that any form of medical treatment has any avail. Many spas, such as Carlsbad, Neuenahr, and Harrogate, make claims to cure cholecystitis, but it is doubtful whether the improvement, if any, is more than temporary. Drainage of the gall-bladder is useless in view of the site of the infection. Cholecystectomy is said to be a dangerous operation, but in experienced hands there is hardly any danger, and, so long as the condition is uncomplicated, the risk is limited to post-operative chest complications, which can generally be avoided by careful choice and preparation of the patient.

INFECTION OF THE MESENTERIC GLANDS.

There is one form of indigestion to which I have drawn attention that is worthy of notice. It results from infection of the mesenteric glands, and is generally tuberculous in character. Though it usually affects children, no age is exempt, and I have now under my care a case in a man of 24. The glands are infected from the intestine, probably by milk, and though the disease is at first local, the glands may later on become foci for widespread tuberculous disease elsewhere. The symptoms are due to disordered intestinal peristalsis, and consist of short-lived colicky pains not well localized, brought on by exercise, and relieved by heat and pressure. The pain is so severe that children will cry out. Vomiting is unusual. There is no sign of intestinal ulceration. The lesion can be distinguished from appendicitis by the character of the pain, which may occur frequently, but lasts only a few minutes or less. There are never attacks lasting two or three days with pyrexia and abdominal rigidity, such as one sees in appendicitis. Between the attacks the patient is quite well; but, as the condition progresses, caseation with adhesions may occur, and complications of the minor obstruction type may arise, while recovery from the attacks is not so complete, with the result that the patient's nutrition suffers. Three stages are recognized: enlargement of the glands, probably in the early period a simple infection; then caseation; and finally calcification. The caseation stage is the danger stage, as at this period the serous covering is often affected, and adhesions may form, leading to obstruction; while, later still, with the giving way of the gland capsule, widespread peritonitis with massive adhesions leads to a condition in which there is little hope of cure. The glands first affected are those in the ileo-caecal angle, and the predisposing cause is probably a pathological appendix. Treatment is surgical, and consists of laparotomy and removal of the appendix. If any caseating glands are found they should be removed, the greatest care being taken to reperitonize the bed from which they have been removed. Subsequent treatment is on ordinary sanatorium lines, avoidance of milk, unless its bacterial cleanliness is assured, and obtaining either actual or artificial sunlight.

DYSPEPSIA OF THE MIDDLE-AGED.

In conclusion, I would say a few words about the surgical dyspepsia of late middle-age. Here there is only one essential—namely, to disprove the possibility of cancer before any treatment is instituted. This is sometimes very difficult, but failure to do so leads to the disaster of inoperability, which one sees too often in abdominal cancer. The cases one must be most suspicious of are those where symptoms occur for the first time after the age of 50, and in all cases the onset is most insidious. We are not yet in a position to state, even approximately, the life-history of cancer, but I think we shall find eventually that it is much longer than is generally supposed, and that there is a premonitory stage marked by symptoms which at present elude us. We have long suffered under the tyranny of the dead-house, and our textbook symptomatology is that of the terminal stages. Take, for instance, a subject germane to our present inquiry, that of cancer of the stomach. We are still asked to make our diagnosis on certain symptoms—wasting, vomiting, pain, and a tumour—which are all late symptoms, and which, if one only knew the early symptoms, should never occur. We are beginning to recognize some of the early symptoms of cancer of the stomach, of which one may enumerate loss of appetite, loss of energy, a heavy feeling in the epigastrium affected by food, flatulence, and belching—all symptoms which precede pain and loss of weight. In the same way cancer of the colon should no longer be diagnosed by pain, loss of weight, and signs of obstruction. There is a preliminary stage of loss of energy, and variations in the accustomed regularity of bowel evacuations, which might make one suspicious and lead to a minute investigation. Cancer of the pancreas, again, is rarely diagnosed before the occurrence of jaundice. There is only one remedy for this, and it lies in the hands of the family doctor. What we need is a series of cases, collected by general practitioners, of malignant diseases proved by operation, in which all the incidents, however trivial, for which the doctor has been consulted for two or three years before the known onset of cancer are reported and analysed.

Suppose, now, you have a case of cancer of the stomach. You look up the patient's history. You find that, three years before, he came to you saying that he had had a little indigestion. He had, perhaps, been working over his desk, and thought he had got a bit of cramp. A little later he turns up with a story that he has been eating something that disagreed with him, and had had a poor night with epigastric pain. A few months later he says he is not feeling "quite the thing," and could you give him a tonic? Or take a case of cancer of the colon. You find in your notes that perhaps, two years before, the patient had come to you saying that, although he had always had a regular action of the bowels once a day, it had become irregular, and he had had to take a mild aperient. A few months later he turns up saying: "A funny thing happened to me last night. I got a pain in my stomach, and found I was full of gas. It did not last long, but it upset me." And, later still, he complains of occasional diarrhoea, or increasing constipation, and there is another request for a tonic.

If cases were tackled in this way, there would gradually arise, and, I hope, creep into our textbooks, a knowledge of a series of minor incidents which are common to cancer cases, and from which we might learn enough to make us watchful and apprehensive of the occurrence of cancer. We could then adopt those methods of minute investigation which we rely on to detect the early signs of disease.

THE MODERN TREATMENT OF LUPUS ERYTHEMATOSUS.*

BY

H. HALDIN-DAVIS, M.D.,

DERMATOLOGIST TO THE ROYAL FREE HOSPITAL.

THE subject I propose to discuss here is the treatment of lupus erythematosus by means of certain compounds of gold. Up to recent years there was no cutaneous complaint which was more disappointing to deal with than this, but since 1922 the position in regard to its therapeusis has been very greatly improved. Before going into the details, I think it will not be a waste of time if I develop shortly the position of this disease in relation to tuberculosis of the skin. Every practitioner is, of course, well acquainted with lupus vulgaris, the common manifestation of tubercle of the skin. The two names, lupus erythematosus and lupus vulgaris, both with the common denominator lupus, express the clinical similarity of the two conditions, although it is true that it is easy enough to diagnose typical cases of the one from the other.

Lupus vulgaris is a disease of childhood and youth, scarcely ever beginning after the age of 25, and is characterized by the well-known apple-jelly nodules. It is prone to ulceration and has no tendency towards symmetry. Histologically it is distinguished by the usual histology of tuberculous tissues—giant cells, imperfect fibrous tissue, etc. On the other hand, lupus erythematosus is rare before the late twenties, it has no apple-jelly nodules, and clinically it appears merely as a permanent scaly erythema and has a great tendency towards a symmetrical distribution. This tendency leads to the well-known "butterfly" or "bat's wing" formation, stretching from cheek to cheek of the patient, involving the nose *en passant*. In bad cases it often affects the scalp, and, especially when of an acute type, the hands and feet in addition. Histologically it presents no feature beyond a small round-cell infiltration round the blood vessels. But there are intermediate cases which are extremely hard to diagnose accurately. Even Dr. Sequeira, who had an unrivalled experience at the London Hospital in lupus, used at times to confess himself at a loss. It is often very hard to make out the apple-jelly nodules, which may be very small in certain kinds of lupus vulgaris, and in an early case of lupus erythematosus the typical symmetry has not yet had time to develop itself. Lupus erythematosus is, I believe, a good deal commoner than is generally supposed. There are many cases of permanent patchy and scaly erythema on the face which are really cases of this disease but go unrecognized. On the other hand I have had a case myself which, when I first saw it, I thought was typical lupus erythematosus, and which I treated as such, but when the erythematous factors had subsided typical lupus vulgaris was revealed.

The great problem, to which much work and study have been devoted, is the relationship of lupus erythematosus to tuberculosis. As is well known, in addition to real tuberculosis of the skin, such as lupus vulgaris and tuberculoderma, there is an important class of eruptions known as tuberculides, which are supposed to differ from frank tuberculosis in that they do not contain the bacillus itself but are due to the toxins produced by that organism. Such are the eruptions known as lichen scrofulosus, acne scrofulosorum, and Bazin's disease, and possibly the rare acne agminata, and those indefinite lumps known as sarcoids. A large quantity of work has been done to show that lupus erythematosus should really be reckoned as a member of this class. It is true that the subjects of the disease, especially in the acute form, often develop tuberculosis of the lung. Sometimes they give positive reactions to the various tuberculosis cutaneous tests. Ramel, for example, finds that tuberculin gives a positive reaction when injected into a patch of lupus erythematosus. On the other hand, the positive reaction is by no means universal. A good many patients with acute lupus erythematosus have actually died without exhibiting any signs of real tuberculosis, either during life or post mortem. Barber thinks that there are two kinds of lupus erythematosus, one of which is a tuberculide, but the other a streptococcide, and due to some focal infection; most often in the tonsils. He has published cases in which the patients were cured by excision of the infected tonsils, and others in which a positive reaction was obtained by the inoculation of a streptococcal vaccine. The issue is still doubtful.

The form of treatment which I now propose to discuss rather lends support to the tuberculide theory. Gold was first tried in the treatment of tuberculosis almost a hundred years ago, and at one time injections of gold cyanide, of course appropriately diluted, were employed in the treatment of lupus vulgaris, but it was not until 1922 that Martenstein[1] published a series of forty-two cases of lupus erythematosus which he had treated with a new organic gold compound known as krysolgan. This consists of a benzene ring to which the gold is attached through the medium of sulphur. In his results he claimed 66.5 per cent. cures, most of the remainder greatly improved, four unaffected, and, it is true, four made worse. These figures were far better than had ever been obtained before in the treatment of the disease. A few patients had seemed to improve under quinine, either given by the mouth or intravenously injected. Others had been reported as favourably influenced by local application of carbon dioxide snow—a painful, barbarous, and uncertain method, which I myself had long discarded—and a few more cases seem to heal spontaneously. On the whole, however, the disease was a very disappointing one to deal with.

Naturally, after Martenstein's work, the gold treatment was tried by other dermatologists, but it did not spread very quickly, at all events in this country. Even in 1926 an authoritative article by one of our leading lights on the modern technique of treatment of this disease never even mentioned it. However, in the 1927 meeting of the British Medical Association at Edinburgh, Dr. Semon read an article on the treatment by krysolgan, and it appeared from the subsequent discussion that a good many British workers had then tried it, but with results hardly comparable with those of Martenstein. No one claimed more than 30 per cent. of absolute cures, and a good many cases remained uninfluenced.

Meanwhile, however, another compound of gold had become conspicuous in the therapeutic world as a valuable aid in the treatment of tuberculosis of the lung. I refer to sanocrysin. This, as of course you are aware, unlike krysolgan, is an inorganic compound, and is really a double thiosulphate of gold and sodium, very analogous in composition to the well-known "hypo" which we use to fix our photographs with. Originally discovered in 1845, it remained in obscurity until about 1918, when Moellgaard took it up as a treatment for tuberculosis. It occurred to some of us who were disappointed with the results obtained from krysolgan, and who hoped for something better, that possibly, if lupus erythematosus were really allied to the tuberculides, a compound which had shown itself valuable in the most fatal of all tuberculous affections might be of great use in a condition of much lower virulence, but somewhat of the same nature. I tried it myself for the first time on a patient, a man, aged 55, who had made some improvement with krysolgan, but subsequently hung fire. His progress was dramatic. Within two months the whole disease, which had been extensive, causing great swelling of the nose, with large patches on both cheeks, the upper lip, and chin, had disappeared, leaving only a few slight and inconspicuous scars, and I had the pleasure of showing him at the October, 1928, meeting of the Dermatological Section of the Royal Society of Medicine, where the other members had no hesitation in admitting that the disease was cured. I also showed three other patients treated in the same way at the same time. But although the idea of trying sanocrysin occurred to me spontaneously, I cannot claim to have been actually the first to use it in this way. Schamberg and Wright[2] had published already in 1927, in the *American Archives of Dermatology*, a series of cases successfully treated with various gold compounds, including sanocrysin, and I have no doubt that other workers were using it also about the same time. Indeed, it is almost inevitable that, after trying krysolgan, one should cast about for other similar bodies to carry on the good work, if krysolgan has failed.

* A lecture given to the Portsmouth Division of the British Medical Association, January 16th, 1930.

Both these drugs are given intravenously. In most cases this presents no great difficulty, but, as everybody knows, there are patients who seem absolutely destitute of suitable cutaneous veins. Both these compounds are freely soluble in water, and as they are always sent out by the manufacturers in sealed glass ampoules, it is very convenient to dissolve them *in situ* and to draw the solution straight into the syringe to be used for injection. They are both very unstable in solution, and the solution must on no account be kept from day to day. Sanocrysin solution is quite colourless, but it soon precipitates metallic gold, not as a shining metal, but in the form of an impalpable black stain, which it is difficult to remove wholly from the wall of the syringe, and which also frequently leaves a black mark in the skin of the patient at the site of repeated injections. The dose of these two compounds is very different. That originally prescribed for krysolgan was initially 0.015 grain, and the maximum dose was 1.5 grains. In the case of sanocrysin, however, we begin at 0.05 gram, and as much as a whole gram of sanocrysin may be given in one injection. Lately, however, I have given up doses larger than 0.5 gram. When one considers that there are fifteen grains in every gram, it follows that, on the whole, the dose of sanocrysin prescribed is from ten to fifteen times as great as that of krysolgan. Probably much larger doses of krysolgan could be given to many patients with impunity, but one hesitates to exceed the limits laid down by the manufacturers. Personally, I have never had any toxic symptoms following its administration, but several instances where these have occurred have been published. Gold is, as we are all aware, a metal powerful both for good and for evil, and although the benefits from the use of sanocrysin in lupus erythematosus are unquestionable, and I believe that its reputation among those who treat phthisis is gradually becoming enhanced, there is no doubt that it is not a drug to be put in the hands of children.

The clinical response in the administration of these drugs is, as might be expected, by no means uniform for every patient. My practice is always to begin with krysolgan, and a very small dose—that is, 0.015 grain, and gradually work up by weekly doses to 1.5 grains. Not infrequently a distinct improvement is seen after the first one or two doses, but, on the other hand, after about six weeks' treatment progress frequently slackens. I then switch on to sanocrysin, beginning with a dose of 0.05 gram, and gradually work up to either 0.25 or 0.5 gram, occasionally even to a whole gram. Patients who have been favourably affected by krysolgan almost always improve further under sanocrysin. Sometimes the improvement is preceded by a local reaction occurring immediately after the injection, during which the affected areas become redder and slightly heated. In other patients the areas fade gradually and the scaling diminishes without any temporary exacerbation.

As to the ultimate result of this form of treatment, I regret that I have no proper statistical analysis of my cases to set out. I suppose in the last three years I have treated about forty cases. I can remember ten certainly which have been discharged as cured, and have remained cured. The great majority of the remainder have been greatly improved. Some of the lesions have cleared up completely, although perhaps one may remain obstinate or, after apparent cure, relapse has taken place. This much I think I can claim conscientiously, that in every case except one the disease has been arrested and has ceased to spread. When I remember the cases which I used to see in former times, and the inexorable way in which the disease used to invade and destroy the complexions of nice-looking people (and you must remember that lupus erythematosus is commoner among women than among men), I think that much credit must be attributed to the gold treatment. I mentioned above one patient who had grown worse under krysolgan and sanocrysin. Finding that this treatment was unsuccessful I tried neo-silver salvarsan, and I am happy to say that, under this, considerable, and I believe permanent, improvement has taken place. In this case the disease was chiefly on the hands.

Additional evidence of the value of the gold treatment of lupus erythematosus is afforded by the action of the manufacturing chemists. Imitation is the sincerest form of flattery, and since krysolgan was introduced by Schering, other manufacturers have imitated and claim to have improved upon it. There are quite a number of other organic gold and sulphur compounds now on the market, made by various chemists. Among these I may mention aurephos, triphal, lopion, allocrysin. Schering has lately introduced one which is claimed to be a great improvement on krysolgan; it is called solganol, and, like all the others, is said to have increased therapeutic value combined with less toxicity. The maximum dose may be as much as a whole gram, but I have as yet had no personal experience with it.

I must not conclude without mentioning some of the possibly unpleasant effects of these compounds. One, very frequent but unimportant, is a metallic taste in the mouth immediately following the administration. This is a phenomenon common after the injection of many metallic drugs—for example, salvarsan, antimony, and sodium cacodylate. Some diarrhœa occurs occasionally, and there may be a febrile reaction, which soon passes off. More serious are the effects on the skin and mucous membranes. A follicular pruritic eruption is not uncommon, and unless this be regarded as a danger signal and the administration of gold be immediately ceased, it will probably be followed by a generalized exfoliative dermatitis. One such case has occurred in my experience, and gave me considerable anxiety for nearly a month, but it ultimately cleared up, and with it the erythematosus. Another serious complication may be a troublesome and painful stomatitis with a very sore tongue. This may be so bad as to interfere with swallowing and cause the patient to refuse food. In lupus erythematosus this is not of vital importance, but when it occurs in phthisical patients may do great harm.

There is one way in which the risk of the unpleasant accidents may be minimized. All these toxic effects are probably the result of the fixation of gold in the liver cells. If the liver cells are fully occupied by some harmless or beneficial substance they will not be able to take up the metal, consequently it is a wise precaution to give patients who are being treated in this way plenty of dextrose a few hours before each injection. This gives the liver something to do and prevents it getting into mischief. In addition, it is wise after patients have had several injections of their maximum dose to lengthen the spaces between doses to two, three, or even four weeks; and one is encouraged to do this by the fact that often improvement continues to make progress as long as three weeks after the last injection.

I myself feel that gold will one day be held to be at least as valuable in tuberculosis as mercury is in syphilis, and although the time is not yet, I hope I have shown that this is a promising field for further work.

THE STRUCTURE OF THE HUMAN ERYTHROCYTE.

BY
W. E. COOKE, M.D., F.R.C.P.ED., M.R.C.P.LOND.,
(From the Pathological Department, Wigan Infirmary.)

If we accept the definition of structure as "the mutual relation of the constituent elements of the whole as determining its peculiar nature and character," and if we remember that cytological structure is brought into evidence only by alteration of the physico-chemical properties of various parts of the cell contents by the action of reagents, then no apology need be tendered if, to render the constituent elements of the erythrocyte visible, an unusual method is adopted.

Walker and Allen (1927) have shown that Golgi bodies and chondriosomes can be artificially produced by adding lipins—lecithin and kephalin—to certain colloidal and protein mixtures and subjecting them to the same processes as are utilized for the demonstration of Golgi bodies in cells; and Walker (1928) has made out an excellent thesis for the study of these artefacts as a guide to variations of the physiological state and pathological conditions. He has shown that saturation or oxidation of the lipins produces similar pictures in the artificial emulsions as in certain cell states.

FIG. 23.—Illustrates stippling and reticulation obtained with brilliant cresyl blue.

Mention of Professor Walker's work is necessary, because the method of approach to the demonstration of the structure of the erythrocyte would appear, in some respect, parallel. In both, consideration of the lipins plays an important part. The methods differ in that Walker has built up certain cell structures from lipins and deduced from their reactions chemical changes in the normal and pathological cell. The micro-chemical dissection of the erythrocyte, on the other hand, is based on a known reaction of lipins. Advantage was taken of this to unbuild the corpuscle and fix the protein of the stroma so as to render it visible. Bütschli (1894) and Hardy (1899) have shown that fibrillar structure can be demonstrated in stretched films of colloidal solutions by the fixatives used for cells, and Bütschli suggested that some of the fibrillar structure seen in fixed cells was due to pre-existent stresses.

A volume could be written on "the peculiar nature and character" of the erythrocyte, but as we are concerned with the microscopic aspect of its architecture, its homogeneity, shape, elasticity, and the effect of injury will be mentioned, and then only in so far as they assist in the visualization of its structure.

The erythrocyte by the usual staining methods or by dark-ground illumination appears structureless. By incident light, in fresh specimens, the homogeneous biconcave disc is sometimes seen to bulge in the centre, but the bell-shaped corpuscle returns to the biconcave shape. Corpuscles in the capillaries curve as they come in contact with obstructions and elongate under pressure, but quickly return to the original shape when the pressure point is passed. The haemoglobin is contained in the biconvex peripheral ring, and does not vary its position with the movements of the corpuscle. On scission, little, if any, haemoglobin is lost, and the resulting parts assume the biconcave shape of the original cell. In Plate I, Fig. 17, a schizocyte is seen below the nucleated red cell, and its appearance suggests that the haemoglobin is confined to the periphery of the distorted corpuscle. Ehrlich (1881) naïvely explained the phenomenon by saying that it is the nature of the red cell protoplasm to take on this biconcave shape, just as it is the nature of a drop of oil to assume a globular form when split off from the parent bulk. The cut surfaces of the divided corpuscle unite at once; but in the absence of a nucleus there cannot be actual repair except in a purely physical sense. These facts lead one to imagine the haemoglobin to be retained in an invisible spongy stroma which prevents loss on injury and which, by its form and position in the corpuscle, is responsible for the shape. An envelope or membrane containing lipins surrounding the cell completes the mental picture. The shape, elasticity, and the result of scission suggest the presence of stresses within the erythrocyte. How true is this conception, and to what extent it is demonstrable, will be seen later.

There are several problems bearing directly on the question of structure which call for attention. The fate of the erythroblast nucleus, the presence or absence of an envelope or cell membrane, and the basophilic substances found in erythrocytes, must be considered.

I.—THE FATE OF THE ERYTHROBLAST NUCLEUS.

The nucleus of the erythroblast undergoes certain changes which are represented in Plate I. The first generation cell (Fig. 1) undergoes mitosis. Fig. 2 is a polar view of a spireme, Fig. 3 a stage in late telophase, and Figs. 4 and 8 the daughter nuclei in the process of reconstruction.

After reconstruction the nucleus of the second generation cell may disappear by simple karyolysis, by pycnosis and karyolysis proceeding simultaneously, or by a combination of pycnosis, karyorrhexis, and karyolysis. The stages of pure karyolysis are represented from the reconstructing nucleus (Fig. 4) by Figs. 5, 6, 7, 12, and 13. Fig. 13 shows the final remnant of the nucleus before karyolysis is complete, and even at this late stage nuclear structure is still visible.

Commencing at the daughter cell Fig. 8, the stages of pycnosis, karyorrhexis, and karyolysis combined are shown in Figs. 9, 10, 11, 14, 15, and 19. The nuclear chromatin soon becomes aggregated into structureless masses from which particles are separated and scattered irregularly in the cytoplasm. The final stages of this process are seen in the Howell-Jolly bodies in an orthochromasic corpuscle (Fig. 15), and in the Cabot's ring in a polychromasic megalocyte in Fig. 19. Pycnosis and karyorrhexis may take place at any stage and the familiar bizarre forms be produced as in Figs. 16, 17, and 18.

The cells in the photomicrographs are megaloblasts, but similar changes take place in normoblasts. In normoblasts the usual stages in the disappearance of the nucleus are pycnosis and karyolysis. Nuclear structure soon becomes indiscernible and the chromatin particles fused into one dense mass which undergoes solution. The end-result of these processes is the complete disappearance of the nucleus, and the erythrocyte normally enters the blood stream without any trace of chromatin.

This brief survey is necessary because the statement that the basophilic substances—punctate basophilia, diffuse polychromasia, and reticulation—are nuclear remains, continues to be made. The normoblast is sometimes illustrated and described as extruding its nucleus. *The molecular disruption* preceding this phenomenon is very difficult to imagine, and, if it ever does occur, must be the unique example of cellular hara-kiri in biology.

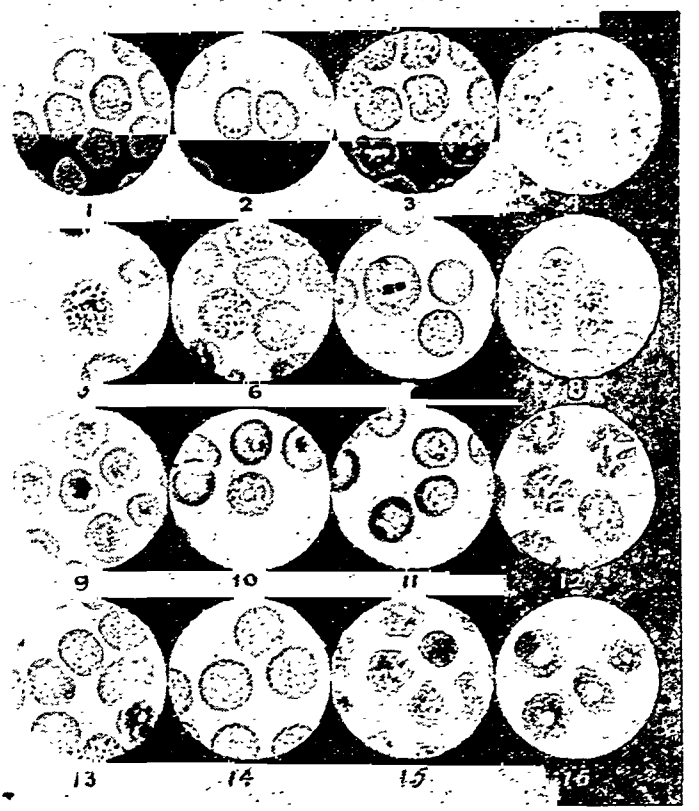

PLATE II.
(Magnification 1,000 diameters.)

FIG. 1.—Illustrates the suggestion of pores obtained by the action of hydrogen peroxide and weak alcohol on erythrocytes.

FIGS. 2, 3, 4, 5, 6, 7, AND 8.—Illustrate various forms of punctate basophilia obtained by the method described in the text.

FIGS. 7, 8, 9, 10, 11, AND 12.—Illustrate various forms of reticulation obtained by the same method.

FIG. 13.—Illustrates two polychromasic erythrocytes obtained as above.

FIGS. 14 AND 15.—Illustrate the spongy stroma of the erythrocyte. Fig. 15 shows the haemoglobin in the process of being discharged.

FIG. 15.—Illustrates the spongy stroma of the erythrocyte with a limiting membrane. In one erythrocyte the haemoglobin is seen leaving the corpuscle *en masse*.

II.—THE ENVELOPE OF THE ERYTHROCYTE.

There is no reason to believe that in its nucleated state the red cell differs from its neighbours and does not then possess a cell membrane. Occasionally, in blood films, there is evidence that an envelope exists. In Plate I, Fig. 20, the envelope of the megaloblast appears fixed at the upper pole and a thin delicate membrane can be traced; but after the nucleus has undergone solution no limiting membrane to the normal erythrocyte can be demonstrated. Rohonyi (1916) and Knaffl-Lenz (1918) deny that there is a true covering membrane because the rate of absorption of ions by pure haemoglobin and by red corpuscles is identical. And if haemolysis with water be observed under dark-ground illumination diffusion of the haemoglobin takes place, but no alteration in the exterior of the corpuscle can be seen. The "ghost" is still homogeneous.

The work on monomolecular films of oil on water commenced by Pockels (1891) and Rayleigh (1899) was applied to fatty acids in solvents, such as ether, by Langmuir (1917). On these lines Görter and Grendel (1925) extracted the lipins of a known number of erythrocytes with acetone and found that the quantity of lipins obtained would cover each erythrocyte with a layer two molecules in thickness. They conclude that there is a bimolecular layer of lipins on the surface of the erythrocyte. They do not take into consideration the possibility of lipins being combined with the protein of the stroma—the lecitho-protein of some writers—but whether their contention is strictly correct or not is immaterial to the present work.

We are forced to the conclusion that the erythrocyte does not possess a cell membrane, but has on its surface a molecular condensation of lipins—lecithin and kephalin. These contain unsaturated fatty acids which are insoluble. If, however, the fatty acids are saturated or oxidized they are rendered soluble in water and dilute alcohol.

If erythrocytes are treated with a mixture of hydrogen peroxide, industrial spirit, and water, the lipin covering is oxidized and dissolved either partially or completely. Partial solution is seen in Plate II, Fig. 1, and the result gives the appearance of pores. The weak alcohol has fixed the cell, but before fixation has become complete oxidation and solution of areas of the covering have taken place.

The benzidine test for blood depends upon the oxidation of benzidine by hydrogen peroxide in the presence of a catalyst. The catalytic agent in this case is haemoglobin. If to the mixture of alcohol, water, and hydrogen peroxide, benzidine be added, we have a means of proving by the blue meri-quinonoid product whether or not the haemoglobin has been reached.

III.—PUNCTATE BASOPHILIA, DIFFUSE POLYCHROMASIA, AND RETICULATION.

The above are the three basophilic conditions described by Ehrlich (1885), but for completeness and contrast Howell-Jolly bodies and Cabot's rings, Plate I, Figs. 15 and 19, deserve brief note. As mentioned in a previous paragraph, Howell-Jolly bodies and Cabot's rings are minute granules of chromatin, and represent the final remnants of the

nucleus. They are visible in fresh preparations by dark-ground illumination and stain purplish red, as chromatin does with methylene blue-eosin dyes, in fixed films. On these grounds I think we may accept them as nuclear remains.

On the other hand, there is every reason to believe that punctate basophilia, diffuse polychromasia, and reticulation (Plate I, Figs. 21, 22, and 23) have no relationship to the nucleus. The arguments for this belief have been the subject of preliminary papers (1928, 1929). The reasons for denying them any connexion with the nucleus are that the conditions are not visible by dark-ground illumination, nor do the staining reactions with methylene blue-eosin preparations resemble those of chromatin.

The abundance of reticular substance in embryos and young animals (Gruner, 1913) and in diseases associated with normoblastic crises, such as Addison's anaemia, von Jaksch's anaemia, and myeloid leukaemia, is not associated with changes in the nucleus (1928). There does not appear to be any connexion between the younger normoblasts and the older normoblasts and the amount of reticular substance. That the basophilic substance is the same in the three conditions is supported by the work of Hawes (1909) and Key (1921, 1924), who pointed out the close numerical agreement between stippled and polychromasic cells and reticulocytes, and is I think confirmed by the following results. If the reagents mentioned in Section II are flooded on to fresh blood films, and the proportions of the reagents altered in the several films, any type of punctate basophilia and reticulation may be produced. In Plate II, Figs. 2 to 8, are seen various types of stippling. The extremely fine granules, coarser granules, and granules of irregular shape, single, and aggregated into clumps, are reproduced, and Fig. 7 shows punctate basophilia with the bar form of reticulation in the same corpuscle. Reticulation is seen in Figs. 7 to 12. The unfragmented granulo-filamentous form is seen in Fig. 9, the fragmented reticulum in Figs. 8, 10, and 11, and the bar form in Figs. 7 and 12.

The granulo-filamentous form of reticulation requires some explanation. Whether demonstrated by brilliant cresyl blue, itself an oxidizing agent, or by the method described above, two facts are apparent. The first is that around

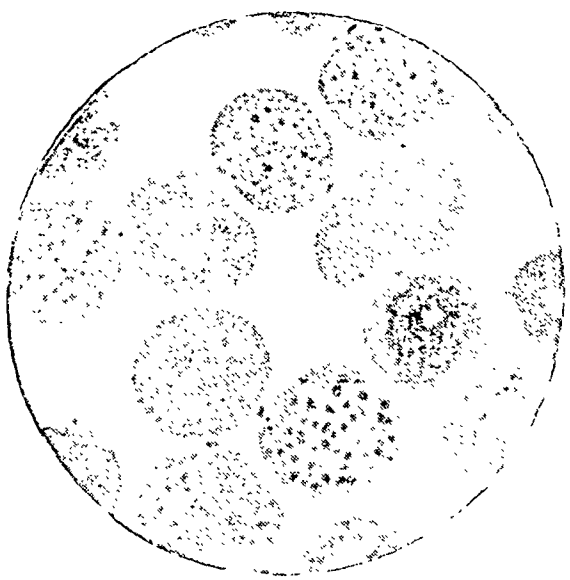

PLATE III.

This is an enlargement of Fig. 13 in Plate II. (× 2,000 diameters.)

the mass of filament there is a pale areola; and the second that the unfragmented reticulum frequently appears in the centre of the corpuscle. The biconcave centre of the corpuscle, being almost devoid of haemoglobin, is the place where one would not expect reticulation if our arguments were sound. There is, however, the fact that no other substance in the erythrocyte except haemoglobin gives the blue meri-quinonoid end-product with benzidine and hydrogen peroxide. The probable explanation is that the lipins covering the centre of the corpuscle have been solutioned and allowed the benzidine and hydrogen peroxide mixture to enter, and at the same time the alcohol has slowly fixed the protein at the periphery of the stroma. The result has been the squeezing out of the haemoglobin into fine strands from the meshwork of the stroma to the centre of the corpuscle where it has come in contact with the reagents. A corpuscle is shown in Plate IV in which the haemoglobin

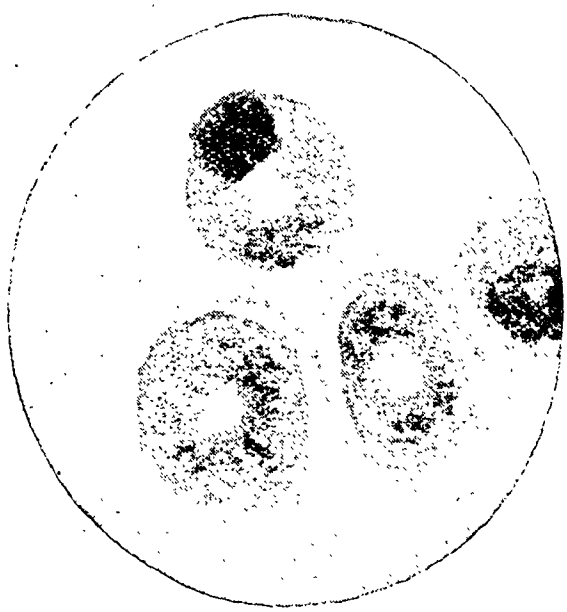

PLATE IV.

This is an enlargement of Fig. 16 in Plate II. (× 3,000 diameters.)

has been expressed into the centre and is being expelled. In fact, this is merely the stage farther than Fig. 9 in Plate II.

Diffuse polychromasia is the most difficult of the basophilic conditions to reproduce artificially. The two cells in Plate II, Fig. 13, of which Plate III is an enlargement, closely resemble the condition except for the surrounding rim of uncoloured substance.

IV.—THE STRUCTURE OF THE ERYTHROCYTE.

In the production of the basophilic conditions the unsaturated fatty acids of the lipin covering of the erythrocyte have been oxidized and partially dissolved, the protein of the stroma fixed by the alcohol, and reaction has taken place between the haemoglobin, benzidine, and hydrogen peroxide. The various stages of the reaction seen in the photomicrographs are explained by the degree of penetration of the lipin covering and the relation between the fixation of the protein of the stroma and the amount of haemoglobin set free before fixation is complete. This is suggested by the corpuscles in Plate II, Figs. 6 and 13, and is better illustrated by Plate III, in which all the stages are seen.

If a larger percentage of hydrogen peroxide and water is used, solution of the lipins occurs and the haemoglobin is discharged. The protein of the stroma, however, is not immediately fixed, with the result that before complete fixation has taken place the colloidal protein of the stroma has filled up the central depression of the corpuscle. This is seen in Plate II, Fig. 14, the previous stage of which is Fig. 15. In the latter figure the haemoglobin is in the process of being discharged, and the protein is seen to have obliterated the central depression.

If the alcoholic solution of benzidine is used undiluted, and the percentage of hydrogen peroxide increased, we have rapid oxidation and solution of the lipins, rapid discharge of the haemoglobin, and rapid fixation of the stroma. The fixation of the stroma protein is so sudden that the central depression is not encroached upon to any great extent. The final result is seen in Plate II, Fig. 16, and in the enlargement of this (Plate IV). The haemoglobin is seen being expelled in a mass from the corpuscle in one of the figures, the spongy stroma is illustrated and fine trabeculae are seen at the periphery connecting the stroma with a faint ring suggestive of a fine covering.

We have, then, our mental picture of the structure of the erythrocyte demonstrated—the condensation of lipin molecules on the surface which acts as a limiting membrane enclosing a spongy stroma in the interstices of which haemoglobin is contained.

Conclusions.

1. The normoblast nucleus disappears by karyolysis or by pycnosis and karyolysis, with or without karyorrhexis, and when the erythrocyte enters the blood stream no trace of the nucleus remains.

2. The erythrocyte does not possess a histological cell membrane, but has on its surface a molecular condensation of lipins which acts as an envelope. Whether or not this is a bimolecular layer, or what physico-chemical relationship between the lipin covering and the protein of the stroma exists, are fields for further investigations.

3. The basophilic conditions of the erythrocyte—punctate basophilia, reticulation, and diffuse polychromasia—are expressions of the same process and vary only in degree. The staining substance is not chromatinic.

4. The presence of these conditions, when obtained by the usual staining methods, would appear to indicate a defect in the lipins on the surface of the erythrocyte.

5. During the course of the work it was noticed that not all blood films behaved in the same manner. Accurate standardization of the reagents and the time, or the employment of other methods on similar lines, might lead to the elucidation of certain problems in connexion with the genesis and life-history of the erythrocyte, and also with its behaviour in disease.

The photomicrographs are by W. E. Cooke and C. F. Hill.

TYPES OF ACUTE MASTOID INFECTION.*

BY

A. J. WRIGHT, F.R.C.S.,

SURGEON TO THE EAR, NOSE, AND THROAT DEPARTMENT, BRISTOL GENERAL HOSPITAL.

While, in what may be described as the classical textbook cases of acute mastoiditis, the diagnosis is easy, experience has taught me that atypical cases are frequent and that, in these, diagnosis is often extremely difficult. It is probable that in all cases of acute middle-ear inflammation the lining of the mastoid antrum and cells participates in the inflammatory process. It is only, however, in those cases in which the inflammation spreads to the bone, owing either to defective drainage or to the intensity of the infection, that the term "mastoiditis" should be properly applied. The early recognition of such a condition is of the utmost importance, both from the point of view of preservation of the hearing and also of the general health.

As an aid to diagnosis, I have tried to classify cases into groups, but, in dealing with them in this way, I wish it to be clearly understood that cases are not infrequently met with showing characteristics of two or more groups in combination.

The Classical Type.

Dealing first with the classical type, there is present a history of recent earache with discharge, and tenderness and swelling over the mastoid process. Fever and constitutional disturbance are present. Characteristically, the discharge has either suddenly ceased with the onset of the mastoid swelling or has been distinctly intermittent in type, being sometimes profuse and sometimes scanty. The periods of diminution in the discharge are generally accompanied by an increase in the pain. In contradistinction to such intermission, the discharge may be continuously very profuse. This profusion indicates involvement of a wide area, and therefore of the mastoid antrum and cells. The character of the temperature chart is of some assistance. Most usually, after a few days' fever, the temperature falls, and then, after a short period, commences to rise again. While this remission, if present, is very significant, not infrequently it does not occur, the temperature remaining high from the commencement of the acute otitis.

A characteristic factor in the tenderness over the mastoid process is that it is confined to one particular spot, and is deep and not superficial. In testing for this the finger should be firmly passed down over the mastoid process while the eye is being watched. The presence of tenderness is always evidenced by a flinch. This obviates, to a large extent, the personal factor of the patient.

Having thus detailed the characteristic symptomatology, it may be said that any, or all, of these symptoms or signs may be absent.

Cases Without Aural Discharge.

Cases presenting signs of inflammation of the mastoid process, but with a normal middle ear, are not infrequently seen. In these a history of previous aural discharge may be present. The explanation is simply that while the middle-ear inflammation, suppurative or catarrhal, has cleared up, the infection in the mastoid process has progressed.

Latent Type.

The characteristic of cases in this group is the triviality of the signs and symptoms, and I can best illustrate this class by a description of a case recently dealt with.

The patient, a clergyman aged 32, following a "cold," had earache with discharge for twenty-four hours only. For two months afterwards he suffered from a vague ache in the ear, with considerable diminution in the hearing and a general feeling of unfitness. During this period the temperature was normal and he was able to continue his duties. The diagnosis of a suppurating focus in the mastoid was made on this history, combined with the presence of a localized tender spot towards the apex of the process, with some opacity and injection of the tympanic membrane. Operation showed pus under tension in the mastoid cells, and drainage produced rapid restoration of the hearing, with return to health.

The difficulty in such cases is to persuade the patient that he has a condition sufficiently severe to need an operation. If left, the suppuration will probably eventually reach the surface and produce manifest symptoms, but complications may supervene.

The points that I have found of most help in diagnosis in this group have been: the presence of a dull ache in the ear; a point of localized tenderness, which may be situated at any portion of the mastoid process; if discharge is present, either its profusion or intermission: the persistence of a defect in hearing of a conductive type; some bulging of the posterior superior meatal wall; and, finally, a haziness in outline of the mastoid cells, in a skiagram, as compared with the other side.

Fulminating or Osteomyelitic Type.

While in the majority of cases of acute mastoiditis the disease will progress for a considerable period without any great risk to life, in the class which I am now trying to describe I believe that early operation is of paramount importance. The cases are associated with a streptococcal infection, frequently haemolytic in type, and, in them, the infection from the beginning widely invades the bone and produces severe constitutional disturbance. They are most commonly met with in association with epidemics of acute sore throat and are due to a spread of infection up the Eustachian tube. There is high fever from the commencement, and the discharge from the ear is unusually profuse, watery, and often blood-stained. Widespread tenderness over the mastoid occurs early. Such cases not infrequently

* Read at a meeting of the Bath and Bristol Branch of the British Medical Association, January 29th, 1930.

develop septicaemia, and the mortality is probably 10 per cent. The infection is these cases does not, however, seem prone to invade the respiratory tract.

The diagnosis is based on the coexistence of an acute sore throat, the high temperature, rapid pulse, furred tongue, profuse bloody discharge, and widespread mastoid tenderness. Early operation is indicated with provision of the freest possible drainage. Scarlatinal antitoxin sometimes seems to be helpful in septicaemic cases.

Mastoiditis in Infants with Enteritis.

It has been pointed out recently that many infants dying of an acute gastro-enteritis show, at necropsy, the presence of an acute otitis media and mastoiditis. It has been suggested that this latter infection is the primary one, and that the gastro-enteritis is a secondary result of the acute toxaemia of the middle-ear infection. I am not prepared to offer any opinion on this, but would only emphasize the importance of examining the ears of infants suffering from any acute febrile infection.

Parotid Mastoiditis.

Cases are occasionally met with in which an inflammatory swelling occurs in front of or above the ear as a result of mastoiditis. Such swelling is often associated with some oedema of the eyelids on the same side, and errors in diagnosis are common. The explanation of such cases is that the infection reaches the surface through cells at the root of the zygoma. If this possibility is recognized the diagnosis can be established by the signs or history of the middle-ear disease, together with the presence of some tenderness over the mastoid process.

Bezold's Mastoiditis.

This is a similar type, in which, however, the swelling occurs in the neck, the explanation being that the suppuration bursts through a cell at the apex of the mastoid process and on the deep side of the sterno-mastoid insertion. The remarks just made as to diagnosis apply here also.

Tuberculous Mastoiditis.

Tuberculosis of the middle ear and mastoid process is usually met with in the infant. In a typical case, it is characterized by occurring in a child of under 1 year with painless and watery aural discharge, enlarged glands around the ear, and facial paralysis on the same side. The infection has been introduced via the Eustachian tube by infected milk.

Spurious Mastoiditis.

Two conditions may simulate an acute mastoid infection—namely, a furuncle of the posterior meatal wall and the so-called herpes oticus.

A furuncle of the posterior meatal wall not infrequently produces a tender swelling behind the auricle. Owing to the meatal swelling, the membrane is invisible and diagnosis may be difficult. If the hearing is relatively good in the affected ear, otitis media is unlikely. The slight degree or absence of fever or constitutional disturbance is also helpful. In addition, tenderness on moving the auricle is suggestive of a furuncle rather than of a bone infection. Sometimes, however, it is impossible to decide whether one is dealing with a meatal furuncle or a mastoid suppuration, except by the performance of an exploratory incision. If, as a result of such incision, it seems reasonably probable that the soft parts only are involved—that is, that one is dealing with a meatal condition—it is important to avoid any interference with the bone, owing to the risk of introducing infection. I can remember a case of infection of the soft parts in which a fatality ensued as the result of opening the bone.

Herpes oticus is the name given to a rare condition, in which herpetic inflammation of the ganglia of the seventh and eighth cranial nerves gives rise to intense pain in and around the ear, with a herpetic eruption on the pinna and in the meatus, facial paralysis, and nerve deafness. The combination of earache, aural discharge from the ruptured vesicles, deafness, and facial palsy, not infrequently leads to a mistaken diagnosis of acute otitis media and mastoiditis. If it is realized that such a condition may occur, it will be recognized.

The diagnosis of an acute infection of the mastoid process, therefore, depends on the recognition of one or more of the many possible signs and symptoms. Pain may be slight or absent. Tenderness is usually present and often strictly localized. Fever and aural discharge are not infrequently absent. Some defect in hearing is more or less constant, and swelling, when present, may be situated behind, in front of, above, or below the ear.

In conclusion, a word or two as to the type of operation to be performed. The object of such operation is to provide drainage. Care should therefore be taken to open up all infected cells. Since, however, the middle ear will recover if not interfered with, it is unwise to pass a bent probe into the aditus to make sure that one has opened the antrum. This proceeding, although commonly done, is extremely liable to dislocate the incus, with resultant permanent damage to the hearing.

It was formerly the practice to pack the operation cavity with gauze and to continue such packing until the cavity had become obliterated. This, in addition to being painful, is unnecessary. In latent cases the incision can be sewn up except for the provision of a small rubber drain at the lower end. In the more acute cases, I find that the best results are obtained by leaving wound and cavity widely open. If, however, instead of filling the cavity with gauze, either thin rubber dam or a strip of oil-silk is used, the pain associated with subsequent dressings is entirely obviated. As soon as the cavity is granulating and showing signs of closing, I believe that there is nothing to be gained by attempting to keep it open with any form of packing.

BRAIN ABSCESS WITH UNUSUAL FEATURES.

REPORT OF TWO CASES.

BY

E. G. COLLINS, M.B., F.R.C.S.Ed.,

HONORARY SURGEON, EAR, NOSE, AND THROAT DEPARTMENT, NORTHERN INFIRMARY, INVERNESS.

BRAIN abscesses may be classified under the three headings of adjacent, traumatic, and metastatic. The two cases which are here recorded belong to the last group, for, although the second case is of aural origin, yet pathologically and clinically it falls into the metastatic class. In both instances the main cerebral infection was contralateral to the original focus.

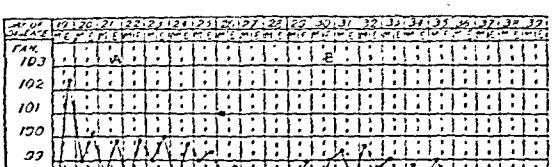
CASE I.

A man, aged 24, was admitted to the Northern Infirmary, Inverness, on May 25th, 1929. Ten days before admission he had received a punctured wound of the right lower eyelid from a garden stake. The wound oozed a little, and he had some headache, especially on the right side, for a few days afterwards. His vision was not affected. He had had a similar accident to the left upper lid ten years previously.

Examination revealed a punctured wound of the inner half of the right lower eyelid extending upwards and inwards for half an inch, but apparently not perforating the conjunctiva. Both lids showed some inflammatory oedema, and pus was present in the conjunctival sac. The bulbar conjunctiva showed chemosis and generalized congestion. The remaining structures of the eye were normal.

Progress Notes.

May 26th to June 3rd: The chemosis and discharge disappeared, but there was some bleeding from the nose, and severe frontal headache, worse at night. He vomited twice. The general condition improved.



June 4th: Pressure below the supraorbital margin revealed considerable tenderness on both sides. No pus was seen in the middle meati, and no oedema or redness of skin over the frontal sinuses. Transillumination and x-ray examinations showed relative obscurity. The diagnosis made was double acute frontal sinusitis, and conservative treatment was ordered.

June 6th to 12th: Headaches not so severe, less tenderness on pressure over the sinuses. He complained of stiff-neck and tenderness of the muscles of the nape of the neck, giving pseudo-head retraction. There was some pain in the epigastrium.

June 13th: The patient was generally irritable. The knee-jerks were not elicited, but the Babinski test gave a flexor response. Some paresis of the right side of the face was noted. At no time was there any convulsion.

June 14th: An exploration was made for orbital abscess, but no pus was found. Paralysis of the muscles of expression of the right side was observed.

June 19th: The patient became drowsy and resented being moved. The tongue was furred. There was now complete paralysis of the right side of the body, gradual in development. Slight tenderness still persisted over the frontal sinuses. The right pupil was rather larger, and reacted more sluggishly. There was slight papilloedema of the right disc, but cerebration too poor to permit determination of the visual fields. The Babinski reaction was extensor, and marked ankle-clonus on the right side was noted. Optic aphasia and perseveration were present; the abdominal reflex was indefinite. Pain was produced by tapping over the left temporal region, but further examination of the nose and ears was negative. Marked emaciation was noticed from the date of the previous examination.

A, Exploration for orbital abscess. B, Lumbar puncture; operation; atropine 1/100 grain, morphine 1/6 grain.

June 23rd: Incontinence of urine and faeces supervened. A lumbar puncture was performed; the spinal fluid was under marked pressure, but clear. The cytological and bacteriological examinations were negative. The procedure was followed by a convulsion, but no further paralysis.

June 24th: Under local anaesthesia a horse-shoe incision was made over the left temporal region, and a flap was reflected downwards. The skull was trephined, and the opening enlarged downwards towards the ear. The membranes were under tension, and no pulsation was present. The dura was incised, and the brain explored; at a depth of 1½ inches about a drachm of thick pus was evacuated. A drain was inserted, and the wound partially closed.

June 25th: Secondary haemorrhage occurred, probably from the dural vessel.

July 4th: The patient died, seven weeks after the accident.

Post-mortem Report.

The brain showed generalized oedema and a temporo-sphenoidal abscess 1 inch in diameter, involving the left internal capsule and spreading towards the base. There was very little attempt at encapsulation. The frontal sinuses were not apparently inflamed, and no pus was present in either of them. No thrombosis of ophthalmic veins was present.

Comment.

At first sight this would seem to be a metastatic brain abscess originating from the septic focus in the right lower eyelid and carried through the circulation to the left cerebral hemisphere. A consideration of the usual characteristics of metastatic brain abscesses reveals, however, some unusual features.

Well-Engleton,[1] in his monograph, states that metastatic brain abscesses have an apoplectic onset, and are usually situated in the white substance of the brain. It is true that this apoplectic stage may be of very short duration, but careful watch was kept in this case for that symptom.

There would appear to be three possibilities for the spread of infection in this case.

1. An examination of the anatomy of this area shows that the veins of the lower lid join the angular vein, which passes through the foramen caecum to enter the superior ophthalmic vein, and thence the other venous sinuses. Experimentally[2] it has been shown that, in the presence of a disturbance of the circulation such as a thrombosis the flow from one venous sinus to another may follow abnormal paths. It would therefore be possible for a retro-thrombophlebitis to spread by this vein to the left cerebral hemisphere. This route of infection is mere conjecture, as specimens for pathological examination could not be obtained. On its assumption, however, it would seem that the condition that was taken to be a double acute frontal sinusitis was really a thrombosis of these veins, causing the frontal headache and pain on pressure over the sinuses. This would account for the absence of any macroscopical changes in the frontal sinuses.

2. The second possible route of infection is from the frontal sinuses. Infection may have occurred here, and a thrombosis of the veins which drain these sinuses have followed, leading to the left-sided brain abscess by a retro-thrombophlebitis. In this eventuality, owing to the absence of any macroscopical changes in the sinuses, we must assume that the sinusitis subsequently cleared up.

3. The third possibility is that the infection was purely haematogenous; although some of the usual phenomena were not observed, this was owing to their transient nature.

I am indebted to Dr. T. Chalmers, under whose care this patient was admitted, for permission to publish this case.

The second case which I am reporting is of interest more from the clinical picture it presents than from any pathological consideration.

A woman, aged 21, was admitted to the Northern Infirmary on September 27th, 1929. She had had an intermittent discharge from the right ear since an attack of measles at the age of 7. Since August the discharge had been worse, and she had had pain in the right ear from the fortnight preceding admission. Two days before admission her local doctor was called in because she was feverish. He found she had a temperature of 104° F., and on examination of the ear he pulled out a piece of cotton-wool and obtained a copious discharge of foul-smelling pus. The evening previous to admission he had noticed some mental confusion. The patient, who had recently graduated M.A., was of considerable intelligence.

Examination showed that the tongue was coated and there was sordes in the mouth. The right drum showed destruction in its lower half; some granulations were present on the inner tympanic wall, and there was a suspicion of cholesteatoma present. The discharge was moderate in amount, and of foul odour. No bulging of the posterior meatal wall was observed, but there had been a recent furuncle there. No mastoid tenderness was present; she heard a whisper at 3 ft. The left ear was normal.

The patient showed marked mental confusion and could not reply to questions, although it was obvious that she understood them. She appeared to have lost all memory for words. Given a pencil she indicated its use, although not able to state its name. Asked her own name, she understood the question, but gave a little nervous cough, and could not reply. She wrote in a good hand, but the letters formed a mere jumble and made no sense. The abdominal reflex was present, and a Babinski extensor response; there was no real Kernig sign, but a slight head retraction. The pupils were equal and reacted to light. A suspicion of facial paresis was noted on the right side. No dysdiadokokinesis and no difference in the pull of the two hands could be detected; past pointing was normal. She had vomited that morning.

A lumbar puncture was performed; the cerebro-spinal fluid was not under pressure. It was sterile, and slightly turbid, and the cell count was 580 per c.cm. The blood film showed a leuco-cyto-sis—90 per cent. polymorphs. No growth was obtained on culture.

On the same day an operation was performed under chloroform and ether anaesthesia, the usual post-auricular incision being made. The cortex was thick and sclerotic, with few cells. The sinus bulged far forwards into the antrum, which contained pus and cholesteatoma under pressure. There were a few granulations on the sinus wall, otherwise it appeared healthy. The dura of the middle fossa was exposed, and found to be bulging, but there were no granulations present on its surface. The radical mastoid operation was completed, and the cavity, after cleaning, was packed with eusol gauze; 100 c.cm. of 10 per cent. hypertonic saline solution was injected intravenously at the conclusion of the operation.

Progress Notes.

On September 28th the condition was unaltered; the packing was removed from the ear, and the temporal lobe was explored, but no pus was found. A further 100 c.cm. of hypertonic saline solution was given intravenously. The temperature was 101° F. and the pulse 124. In the afternoon the patient was very restless and had a slight convulsion, but did not lose consciousness. The temperature was then 102° and the pulse 160.

September 29th: She had a convulsion at 2 a.m. lasting two minutes, with twitching of face and arms; she was very restless, but quite conscious. The temperature was 100° and the pulse 124. The wound was dressed, and a further 50 c.cm. of saline solution was given. In the evening the cerebral irritation became more

marked, and the patient died at 11 p.m. She was conscious until the last half-hour.

Post-mortem Report.—The brain showed generalized oedema, and the abscesses were present in it as follows. (1) A large subdural abscess covered the whole surface of the superior part of the left hemisphere, extending towards the base, and especially marked at the anterior part of the frontal lobe. (2) A left frontal lobe abscess, half an inch in diameter, contained thick grumous pus. There was some attempt at encapsulation. No stalk connecting it with the subdural abscess was found. (3) A right temporal lobe abscess, three-quarters of an inch in diameter, was situated nearer the occipital lobe, and not immediately adjacent to the mastoid region. This appeared to be more recent than the frontal lobe abscess, as there was very little attempt at encapsulation. The left mastoid and the sinuses showed no evidence of infection.

Comment.

It is obvious that the history given of this patient's illness was totally inadequate, but further inquiry from her doctor and relatives failed to elicit any other facts.

The case was diagnosed as meningitis, with the suspicion of a right temporo-sphenoidal abscess, but the possibility of a contralateral brain abscess was not seriously considered. The facial paralysis was taken to be due to involvement of the nerve in its canal, and not to a cortical disturbance. It was the only real localizing sign present, and in view of the post-mortem findings this is rather remarkable, as there must have been considerable pressure over the whole motor area from the very large subdural abscess. The infection here was haematogenous, but again we were unable to obtain any history of an apoplectic onset. Since the cerebral condition was of several days' or weeks' duration, during which time the patient was not under medical observation, this fact may be discounted. The duration of the illness would also account for the fact that the blood cultures were sterile, as organisms are soon eliminated from the blood once the cerebral infection has commenced. The findings in the cerebro-spinal fluid are what one would expect in view of the pathological findings.

The aphasia stands out pre-eminently in the clinical picture. This should have directed our attention to the left hemisphere, especially when we had ascertained that the patient was right-handed. It differs, however, in some respects from the aphasia observed in a temporo-sphenoidal abscess of the left side. Obviously several of the higher centres[3] were involved, and if we analyse her symptoms we can pick them out.

1. She had a motor aphasia, since she could not repeat sentences, or, indeed, speak at all. This centre is usually said to be located in Broca's area; Marie and Head contend, however, that motor aphasia is not caused by interference with a specific area or tract, but that the area of the cortex involved is in relation to the squamous suture.

2. Whether she had a partial word-deafness is more difficult to determine, owing to the above symptom. At any rate, she had not a total word-deafness, since some questions asked were certainly understood.

3. She had a sensory agraphia, since she could not write a sensible sentence; this centre is in the angular gyrus. It does not appear that she had a word-blindness (alexia), which would have indicated involvement of the second occipital convolution.

4. There was probably involvement of some of her association tracts, but this is impossible to determine.

It is rather remarkable that with a subdural abscess of such a size the patient remained conscious until the end of her illness. One would have expected her to be far more drowsy and comatose than she was.

The post-mortem findings call for little comment. Jobson[4] and others have recorded cases of contralateral brain abscesses, but it would seem that these were not true metastastic abscesses, but rather due to a retro-thrombophlebitis. I have been unable to find a reference to a chronic otitis causing metastatic abscesses in the brain, without showing any other evidence of the generalized pyaemia, but no doubt it has occurred.

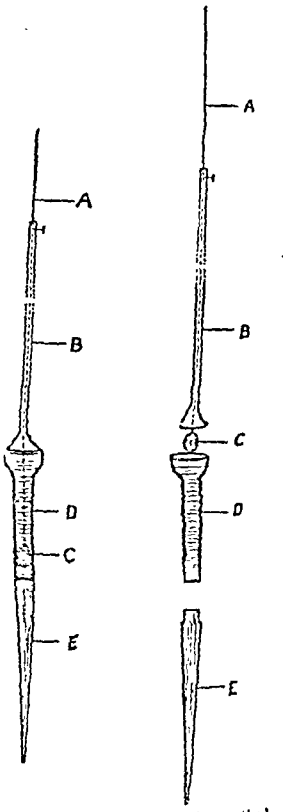
A SIMPLE AND SAFE METHOD OF OESOPHAGEAL INTUBATION.



BY

COURTENAY YORKE, M.D., B.S., F.R.C.S.,

HONORARY AURIST AND LARYNGOLOGIST TO THE LIVERPOOL STANLEY HOSPITAL.

A PATIENT reduced to fluid nourishment is immeasurably better off when he can take this by the mouth than when he must receive it directly into the stomach—in other words, a tube in the oesophagus is far preferable to a tube in the stomach, all things being equal. This qualification is necessary since intubation of the oesophagus may involve difficulty and danger in the introduction of the tube, and discomfort and uncertainty afterwards. Unless these defects of intubation can, to a great extent, be eliminated the procedure will not commend itself as a substitute for gastrostomy. It is the purpose of this short communication to describe a method of intubation which in large measure, I think, disposes of these objections.

In the first place, several concessions to gastrostomy should, in my opinion, be made. Gastrostomy is, I consider, the best treatment when the stricture is at the cricoid end of the oesophagus, and, except as an emergency or in special circumstances, it is preferable to the use of long flexible feeding tubes which extend from the mouth to the stomach, and to the use of those made of perishable material, or of such as are employed with anchoring threads in the mouth. After conceding so much to gastrostomy, however, there still remains a considerable field for intubation in those cases where the obstruction is in the thoracic part of the oesophagus or at the cardiac end, and especially where the growth is not very extensive and where the condition of the patient is good.

The drawings illustrate the method of intubation described. A, Wood-carrier. B, Cannula. C, Wool plug. D, Souttar's tube. E, Gum-elastic tip.

The suitability of the case for intubation having been determined, the object in view is to traverse the stricture with a tube of suitable size by means of a technique that is as quick and simple and safe as possible. The best tube to use is the one devised by Souttar. Being a closed spiral of wire it is flexible and it is made with certain tortuosities which favour retention. The average length of the tube should be about 2¼ inches, but on occasion a longer one up to 3 inches could be used. The lumen should not exceed 6 mm. at the lower end and 10 mm. at the expanded end. The larger sizes of Souttar's tubes I consider dangerous, requiring as they do considerable stretching of the friable stricture and the use of a very large oesophagoscopy tube.

The essence of the method of intubation now to be described is the fitting on the lower end of the tube of a gum-elastic tip which guides the tube safely and surely through the stricture, and then, having done its work, is disengaged from the tube and passes down into the stomach and intestines. The gum-elastic tips are conical in shape and about 3½ inches long. Their bases are specially made to fit into the lower end of the tubes, the latter being filed

so as to make the union perfectly smooth and uninterrupted. The appliance for introducing the tube serves also for expelling the gum-elastic tip. It consists of a very slender rod enclosed in a cannula. The latter is expanded and flattened below and is perforated for a screw above. The former has fine hooks and a thread at its lower end to serve as a wool-carrier.

To prepare the equipment for use the following procedure is necessary—namely,

1. Lightly fit the gum-elastic tip to the tube; on no account must the union be firm, as it requires to be easily broken when the tube has been placed in position.

2. Affix wool to the wool-carrier in bulk sufficient just to engage the lumen of the tube and support its weight.

3. By means of the screw adjustment extend the wool-carrier so that the little wool piston just touches the gum-elastic tip when placed inside the tube, whilst at the same time the flattened lower end of the cannula makes contact with the tube.

4. Fix the wool-carrier in this position by tightening the screw.

The apparatus being assembled and prepared in this way is ready for use. The oesophagoscope is now passed and the face of the stricture brought into view. One or two rubber-tipped Jackson's bougies are now passed to dilate the stricture and to determine the exact position. Everything is now ready for passing the tube. The gum-elastic tip, being soft and pliable, easily and safely finds its way through the stricture, carrying with it, harmlessly and unerringly, the metal tube. When the expanded upper end of the tube reaches the face of the stricture the downward movement is discontinued and the gum-elastic tip expelled. This is achieved by loosening the screw which fixes the wool-carrier, so that it is free to push out the tip. After so doing the final step consists merely in withdrawing the wool plug into the expanded upper end of the tube. In doing this the tube must be held in position with the flattened lower end of the cannula until the wool plug, having reached the tubal expansion, is quite free and the introducing mechanism comes away unimpeded. It will be seen that the use of the oesophagoscope is unfortunately essential, but the actual placing of the tube is easy and safe, only requiring one simple action and occupying but a few seconds.

The efficiency of Souttar's tubes is surprising. Even the smallest size, with a diameter of 4 mm. at the lower end, is fully adequate for fluids and may continue to function well for months. Trouble can arise from displacement of the tube downwards or obstruction of the lumen. I have little experience of displacement upwards of Souttar's tubes, but on a number of occasions I have known a tube to work its way harmlessly through the stricture and pass into the stomach.

The maximum length of service of an intubation tube is obtained when the largest size possible, within the limits previously stated, is used, and when nothing but thin fluid nourishment is given, succeeded on each occasion by a drink of water to flush out the tube.

All the appliances referred to in this communication are made by Messrs. Mayer and Phelps of London.

COMPARISON OF A THOUSAND SERUMS TESTED BY THE WASSERMANN AND KAHN METHODS.

BY

H. A. COOKSON, M.B., F.R.C.S.Ed., D.P.H.Cantab.,
PATHOLOGIST, ROYAL INFIRMARY, SUNDERLAND;
AND
K. S. BROWN, M.B., Ch.B.,
ASSISTANT PATHOLOGIST, ROYAL INFIRMARY, SUNDERLAND.

In the series of investigations of 1,000 serums now reported the Wassermann technique used was that devised by Colonel Harrison; Kahn's technique[1] was closely followed, as laid down by the inventor. The antigen was supplied by Messrs. Parke, Davis & Co., London. An attempt was made to use symbols in expressing the comparative strengths of the reactions in either case. A list of equivalents is given in Table I.

TABLE I.—*Comparative Strengths of the Kahn and Wassermann Reactions.*

Reaction.	Comparative Strengths.				
Wassermann	++	+±	+	±	−
Kahn	++++	+++	++	+	−

For diagnostic purposes the two tests were in agreement in 98.4 per cent. of cases, and they appeared to be of equal strength in 94.6 per cent. In 3.8 per cent. the cases showed quantitative differences; 40 per cent. of these were treatment cases. In 87 per cent. the Wassermann reaction appeared to be the stronger of the two. Disagreement between the two tests was apparent in only 1.6 per cent. of the 1,000 cases; these are listed in Table II. Of these, it will be noted that 50 per cent. are treatment cases, and that the Wassermann test appeared to be the more sensitive. In two doubtful cases—one of general paralysis, and another of pernicious anaemia—the serums were in bad condition, and the results should not, perhaps, be included. In both instances, unfortunately, we have no further knowledge of the cases.

TABLE II.—*Disagreements.*

Clinical Description Given.	Wassermann Reaction.	Kahn Reaction.
Gonorrhoea and pregnancy	+	−
? Congenital syphilis...	−	+
Treatment case	+	−
Previous ++ (Wassermann reaction) treated	±	−
Arthritis case	Trace	−
Treatment case	±	−
Ulcer of lip	+	−
Treatment case	+	−
Treatment case	+	−
? General paralysis	−	++++
Previous positive (treatment case)	−	+++
Treatment case	±	−
Rash and alopecia (four months)	+	−
Addison's anaemia	−	+++
Treatment case	±	−
Adherent placenta	−	++

Summary.

1. This series would seem to suggest that the Kahn test and the Wassermann reaction can be fairly strictly compared.

2. In this series the results are in favour of the Wassermann reaction.

3. It is valuable to test a serum by both methods.

4. The convenience, simplicity, and rapidity of Kahn's method make it a very useful test where conditions would render a Wassermann test difficult or impossible.

5. The Kahn test should not supplant the Wassermann.

6. The Kahn test is more difficult to read, and is more affected by external temperature than is the Wassermann test—that is, apart from tropical conditions.

ARTIFICIAL PNEUMOTHORAX.

BY

JAMES D. MACFIE, M.B., CH.B.GLAS.,
SENIOR RESIDENT MEDICAL OFFICER, WINSLEY SANATORIUM;
AND
GEORGE NAPIER, B.Sc., M.B., CH.B.ST. ANDREWS, D.P.H.,
ASSISTANT RESIDENT MEDICAL OFFICER, WINSLEY SANATORIUM.

ARTIFICIAL pneumothorax is comparatively easy to induce; the immediate death rate is low, and the continuance of treatment interferes little with the patient's vocation. The results contrast favourably with those of untreated cases of equal severity. The only drawbacks to the use of this treatment by the general practitioner are: (1) lack of *x*-ray apparatus—a very valuable, if not essential, adjunct to this procedure; (2) the difficulty of selecting suitable cases, on which the whole success of the treatment depends; and (3) the lack of a definite course on tuberculosis in many of the medical schools.

It is not possible to induce artificial pneumothorax in every case. There must always be a percentage of failures, depending on the type of case selected and the number of doubtful cases tried. The percentage of deaths later on among artificial pneumothorax failures will give some idea of the range of cases attempted. The two chief causes of failure are extensive adhesions and pockets. In our experience the treatment is of little use in these as the collapse is negligible. We consider that the only way to say whether or not a pneumothorax is possible is by trying it. The *x*-ray appearance and the movement at the costo-diaphragmatic angle may be useful, but can in no way displace the trial by needle.

The probability of the occurrence of pleural effusion is quite outside our prognostic powers. Whether this fluid is due to tubercle, local anaesthetic, cold air, too much gas, and so on, we have found it quite impossible to say. We agree that the prognosis is not ultimately worse, but we do not agree that it is improved. The mental effect is very detrimental, and during the fever the patient's condition may be rather alarming. The loss of weight in a large percentage is at the beginning noticeable, probably owing to altered metabolism caused by purely mechanical intervention, and in some cases displacement of the mediastinum.

The results of combining sanocrysin with artificial pneumothorax treatment have not been what we expected. Sanocrysin in our hands has been, we think, a failure. We believe that, possibly, on the whole we delay too long before inducing a pneumothorax—not using this method till we are honestly convinced that there will be little response to the usual treatment. This is probably better than indiscriminate advocacy of the method. At present we operate on no really early case. We have found no material change in the blood pressure attributable to this treatment.

STATISTICS OF 111 CASES.

End-Results of 89 Successful Inductions, 1924–29.

Period since Induction	No. of Inductions in Period.	No. of Cases Alive.	No. of Cases Dead.	Percentage Alive Now.
Under six months	17	16	1	94.0
Six to twelve months	10	9	1	90.0
Twelve to eighteen months ...	11	6	5	54.5
Eighteen months to two years ...	15	8	7	53.3
Two to three years	23	10	13	43.5
Three to five years	13	6	7	46.0
Totals	89	55	34	

Number of successful inductions 89 = 80 per cent.; number of failures 22 = 20 per cent.

Percentage of cases alive out of inductions which took place: over one year ago, 58 per cent.; over two years ago, 44 per cent.

Generally it seems to be better for the patient to have one physician the whole time through, especially if there is anything out of the common in the psychology of the patient or in the technique of the case. We try never to vary the diet of a patient who has either haemoptysis or fluid, if we can avoid it.

Immediate Results. On Discharge from the Sanatorium.

Eighty inductions were successful; of these 14 died or were given up = 17.5 per cent.; 66 left the sanatorium with prospect of further refills. Of these 66, 44 were improved and 22 showed little or no improvement. Of the total inductions, therefore, 55 per cent. left definitely improved.

Of the improved cases, as regards weight, 3 remained stationary, 17 gained weight, 22 lost weight, and 2 were doubtful. Of the improved cases, therefore, 50 per cent. lost weight, in most cases slight.

Analysis of 12 Cases (3 Male, 9 Female) at Present in the Sanatorium.

Haemorrhage was the reason for induction in 4 cases. Two of these patients had temperatures usually over 100° in the evening for some weeks, and one reached 102.8° on occasions. The two others had no high temperatures, but frequent small haemorrhages. The average refill in these four patients (all women) was 450 c.cm.; the average end-reading 0 + 8, 2 + 8, 3 + 8, and − 2 + 4. In none has haemorrhage been repeated after the third refill, and they are all up and about as we write.

Active disease, almost confined to one side, was the reason for induction in four cases. Three of these patients had done extremely well, and the other one has definitely improved. All run normal temperatures.

Disease on both sides, more extensive on one, was the reason for induction in the remaining four cases. Of these patients, one shows little or no improvement, one shows slight improvement, and two have definitely improved. Three of the four run normal temperatures as a rule.

Points of Importance or Interest regarding Inductions or Refills.

Inductions.

Do not keep the patient in suspense between deciding on the induction and doing it.

The technique should be simple and speedy. The sooner the needle is in the chest the better.

Morphine is in most cases unnecessary: it upsets the patient and makes him more apprehensive than need be. No preparation at all is necessary.

The operation should cause extremely little pain. Novocain is probably the best anaesthetic. It is more important to anaesthetize the pleura than the skin.

We use the sharp needle for inductions, and have never had any trouble with it.

The idea of pneumothorax, suitably explained, appeals to the average patient, and consent to the operation is not difficult to get.

X-ray treatment is extremely useful before, during, and after the employment of artificial pneumothorax.

The air should be run in slowly, and only 300 to 400 c.cm. given the first time. If the patient is nervous, give even less

The site of puncture will vary with each case. Where a first puncture is unsuccessful another may be tried at the same sitting, and three more if necessary on a future occasion. When the procedure succeeds it usually does so before then.

The air should not be introduced before there is reasonable certainty that the needle is in the pleural cavity.

The single manometer, *plus x* rays, is quite satisfactory for the average case.

In doubtful cases the patients should be warned that failure is probable.

Refills.

It is better to exceed rather than to let the number of refills be insufficient. Large refills are to be avoided.

The optimum pressure should be found as soon as possible and maintained.

The intervals must vary in each case; fix the optimum pressure and endeavour to maintain it over the greater part of the period. Give a refill at once on any signs of renewed activity.

The patient should for some time rest on the day of refill; we generally keep patients in bed for the remainder of the day. We never let a patient up all day at once after the induction, no matter how good the temperature, but gradually increase the time allowed.

Artificial pneumothorax may be abandoned at any time. It should be remembered that though the treatment does throw an extra strain on the sounder side, this may be partly neutralized by rest in bed, and by the removal of general toxaemia due to the bad lung, which undermines the resistance and retards the healing of the better side.

Toxic cases do best.

The side on which the operation is done, whether right or left, seems to have little or no influence on the result. We have about equal proportions of good and bad on either side.

Treatment of Fluid.—Fluid is a very common accompaniment; in a large percentage of our cases fluid appeared at one time or other. Where the amount is small it is as well to leave it alone; where it is large and upsets the appetite we remove it. We have had few serious cases of pleural effusion—that is, where the fluid became infected by other organisms.

Shortness of Breath.—It is surprising how soon the average patient gets accustomed to artificial pneumothorax treatment, and how little distress it causes him.

Loss of Weight.—Though about 50 per cent. of the patients lose weight, this has little influence on the ultimate prognosis.

Return to Work.—It is difficult to state with accuracy the number of cases fit for work, as this depends so much on the type of work the patient attempts to do, his home surroundings, and his employer, etc. Again, many of the patients are women who are occupied with light housework. A good number of the men we know are engaged in rather heavy work, and doing quite well at it.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

CONGENITAL OBSTRUCTION OF THE POSTERIOR URETHRA.

THE case here recorded is of interest because of the peculiar condition of the skin, and also owing to the absence of dilatation of the ureters and of hydronephrosis, although the bladder wall was much thickened.

This case is that of a male child, aged 3 days, admitted to Dr. William Johnson's ward at the Royal Liverpool Children's Hospital on March 7th, 1929, with the history that there had been no micturition since birth. The birth was normal and the child passed meconium three times before admission to hospital. Circumcision was performed the day before admission, but no urine was passed subsequently. The parents were healthy, and there was one other child, a healthy boy. The child was apparently full term. The remnant of the umbilical cord showed no signs of infection. The whole skin of the body was in a condition of solid oedema, with absence of pitting on pressure. The limbs were stiff, as if in rigor mortis. Nothing abnormal could be detected in the heart, lungs, or abdomen. The child was drowsy and refused its feeds. Death occurred a few hours after admission, no urine having been passed.

Post-mortem Examination.—There were no external structural abnormalities. The skin condition was as described above. The kidneys were smaller than normal, congested, and tough on section. The capsule of each kidney was more adherent than normal, but not so adherent as to tear the kidney substance on stripping. The surface of the kidney was smooth. The cortex and medulla were of normal proportion, and of normal appearance to the naked eye. There was no hydronephrosis. The ureters were not dilated, but the wall of the lower end of the right ureter was thicker than normal. The bladder wall was one-third of an inch in thickness, both epithelial and muscular coats being thickened. The bladder was not dilated, but contained about one drachm of thick yellow urine. There was a septum in the urethra, immediately distal to the verumontanum. The passage of the finest probe was not possible either way. The septum was apparently complete, and not valve-like in type. The urethra distal to the septum was of normal calibre, but the proximal urethra was dilated, and an ordinary lead pencil could be passed from the bladder up to the obstruction. There was nothing abnormal found in other organs. Microscopical examination of the kidneys showed slight generalized fibrosis, with hyaline swelling of the glomeruli, but the tubules were of normal microscopical appearance.

Young, Frontz, and Baldwin (*Journal of Urology*, October, 1919, vol. iii) report twelve cases of congenital obstruction of the posterior urethra observed at Johns Hopkins Hospital, the youngest patient being 11 days old. They have also collected twenty-four cases from the previous literature. In the latter series two infants died shortly after birth, and the necropsy revealed a valve at the lower end of the verumontanum, with dilatation and hypertrophy of the bladder, dilatation of the ureters, and hydronephrosis. One case recorded by them is that of a foetus (5 to 6 months) with a similar condition, and another case is that of a still-born child. The other cases were of infants and older children.

A CASE OF SCLEREMA NEONATORUM.

SCLEREMA neonatorum occurs so rarely that the following case seems worth recording.

On Christmas Day a 4-para in the early stages of acute pneumonia was delivered of a premature male infant weighing about 5 lb. The infant, though small, was vigorous. On the second day the nurse called my attention to a slight swelling of the foreskin and a bluish patch of induration on the right buttock. Urine was freely passed. In a few days the induration extended all over the infant's body, limbs, and face, and at this stage his body was more or less rigid. The eyes could not be opened and sucking became impossible. There was regurgitation of fluid through the nose, with development of snuffles and a haemorrhagic discharge. Crying ceased, respiration became slow, and during the last hour of life blood came freely from the nostrils with every breath. The induration was of a peculiar icy blue colour. There was no pitting on pressure. The skin felt hard and could not be pinched. The temperature was subnormal.

I believe the etiology of this disease is little understood. One view is that it is a coagulation or degeneration of the subcutaneous fat in premature infants which some authors attribute to external cold. In the case above described it may have been due to a toxin derived from the placental blood. It is interesting to note that though the mother made a rapid recovery lactation never appeared, possibly owing to atrophy of the fat-producing cells of the secreting acini.

Smethwick, Staffs. E. CONDON, M.B., B.Ch., B.A.O.

PERFORATED DUODENAL ULCER.

THE main points of interest in the following case of perforated duodenal ulcer are (*a*) the patient's advanced age, (*b*) the short history of gastric symptoms, (*c*) the absence of malignant disease, and (*d*) the patient's easy convalescence and subsequent good health.

The patient, a man aged 75, was admitted to Croydon General Hospital, on March 26th last, with a history of three days' "indigestion"; previously his digestion had been good. Seven hours before admission he had sudden severe pain in the epigastrium, followed by repeated vomiting. When we saw him he was collapsed; he had a dry tongue, brown in colour, and a rigid abdomen. His temperature was 97° F., and his pulse rate 72. The heart, lungs, and urine were normal. A diagnosis was made of acute perforated gastric ulcer.

With the patient under gas and oxygen anaesthesia the abdomen was opened, and a small perforated ulcer, simple in character, was found in the first part of the duodenum. The ulcer was invaginated with a purse-string suture, free fluid was swabbed out, and the abdomen closed without drainage. The operation was completed in about twenty minutes.

Twenty-four hours after the operation the patient was given small feeds by the mouth, and a week later he was allowed to sit up out of bed. Convalescence was uninterrupted, and on April 15th he was discharged, having been given instructions about his diet and the advisability of taking alkaline medicines. Since then he has gained about 10 lb. in weight, and has had no abdominal discomfort. He is still careful about his food.

I have so far failed to find in the literature any reference to a case of simple perforation in a patient of such advanced age. In a similar case, of which an account was published in the *British Medical Journal* of July 20th, 1929 (p. 109), the patient's age was 70.

I am indebted to Mr. E. M. Cowell, the surgeon in charge of the case, for permission to publish these notes.

Resident Medical Officer, Croydon General Hospital.

Reports of Societies.

TREATMENT OF SYPHILIS.

AT a meeting of the Medical Society of London, on February 24th, with Mr. DONALD J. ARMOUR in the chair, Colonel L. W. HARRISON opened a discussion on the treatment of syphilis.

Colonel Harrison said that, in discussing so large a subject, he could only make some general observations; he would deal first with the treatment of the disease in its early stages, and afterwards with the treatment of later manifestations. Recent experiments on rabbits, conducted by Brown and Pearce in America, had thrown some light on the disease in man. These workers had observed the course of the untreated disease, produced experimentally, as well as its course under treatment. Their results showed a series of latent periods alternating with relapses, in the manner of relapsing fever, and similar to those observed in man. Further, the severity of each phase was inversely proportional to that of the phase preceding it; thus a rabbit developing two primary sores by inoculation was less likely to show generalized symptoms, later, than a rabbit with only one primary lesion. If the sites of the primary lesions were excised within forty-eight hours of inoculation, generalized symptoms were more likely to occur; after early interference these secondary manifestations usually arose in bones, but if the excision was made later the bones appeared to have acquired immunity, and secondaries usually appeared in the skin; interference still later with the primary sore led to the appearance of secondary lesions in the eye, without manifestations in bones or skin. In short, the animal developed a resistance to the disease proportional to the time of interaction between the spirochaete and the tissues. It had been observed frequently in the past that the longer the disease was active in man or animal the less likely was reinfection by reinoculation. This experimental interference with the degree of severity of the primary lesion threw a light on the development of late neuro-syphilis in man; in these human cases there was rarely a history of secondary manifestations, and the primary lesion was often slight. The inference was that at an early stage the virus had spread throughout the body, including the central nervous system; changes in the cerebro-spinal fluid, which occurred in some cases before the serum reactions became positive, offered corroborative evidence of this hypothesis. The patient, therefore, had foci of spirochaetes throughout his system in sites of varying accessibility. It could be argued from this that the disease should be allowed to run its course untreated as far as the end of the secondary stage, in order to avoid the later development of syphilis of the central nervous system. But there was evidence that the expected immunity did not always develop, and the longer the spirochaetes were allowed to remain in the tissues the greater became their resistance to remedies introduced into the general circulation. The decision, then, must be in favour of early treatment; but since this meant dispensing with the natural resistance of the patient it was important that the substitute should be thorough in action and sufficient in quantity. The remedies for the early stages fell into two groups: spirochaeticidal agents, and stimulants to provoke tissue reaction. Of the first group, arsenobenzene preparations fell into a class by themselves; while such agents as bismuth and mercury, with others not in general use, such as tellurium and gold, formed a second class. The effects of the arsenobenzene preparations were rapid and transient, but so dramatic that in the early days of their use they were thought to cure the disease in one administration. There was evidence, however, that their action did not reach the central nervous system, or even the organisms buried in the vasa vasorum of the cardio-vascular system. Since the introduction of salvarsan most of the cases of paraplegia, and of paralysis of cranial nerves, had occurred in patients treated with arsenobenzene preparations. He considered that the administration of these preparations stopped abruptly the interaction between the spirochaete and the tissues, and so prevented the development of immunity. In his opinion this explained why the recurrences of syphilis in the central nervous system were much more frequent since the introduction of salvarsan than they had been in the days of mercury. Arsenobenzene preparations were insufficient by themselves, and should be used in conjunction with bismuth and mercury. Mercury was valuable for the variety of ways in which it could be used, though the toxicity of its curative dose was too high to make it a perfect remedy. It had been largely replaced by bismuth, however, for injection, since it was shown by Levaditi that the spirochaeticidal properties of bismuth were greater. Where arsenobenzene preparations were contraindicated the use of a soluble preparation of bismuth established control of the disease, and could be followed by a salt which was more slowly absorbed. Solutions of bismuth, generally speaking, were more quickly absorbed than suspensions of the soluble salt; of the insoluble preparations, those suspended in watery solutions were more evenly absorbed than were those suspended in oil. Liquid paraffin was an unsatisfactory medium of suspension; in his experience the oxychloride of bismuth was well and easily absorbed; this salt, and the subsalicylate, he preferred to bismuth in a state of fine subdivision. He felt strongly that it was a mistake to give a first course of arsenobenzol alone, following it up later with a course of bismuth or mercury. Experience went to show that cases of neuro-recurrence had been those treated with arsenobenzene preparations in the early stages. He believed in spacing out treatment; he usually began with three doses of some arsenical preparation, followed by three of bismuth; he then allowed an interval of two weeks before giving two more. A certain number of cases were intolerant, and developed dermatitis; usually the dermatitis showed a definite incubation period. During the latter part of the course he added potassium iodide to the treatment. Many authorities held that arsenical preparations were contraindicated in cardio-vascular syphilis, especially syphilitic myocarditis, but he did not agree with this view. Trouble would, of course, arise if arsenical preparations were given blindly and the case was not kept under careful observation; but if small doses were given an improvement was to be expected, provided that the patient was not too much of a wreck before treatment was begun. For syphilis affecting the liver, however, arsenobenzol preparations were contraindicated. In syphilis affecting the central nervous system the best results were obtained by feeling one's way; small doses of some preparation should be given twice a week at first, and, later, the remedy should be pushed. In tabes he had obtained his best results from the use of sulpharsenobenzene with bismuth, or silver salvarsan. Tryparsamide gave uncertain results in general paralysis of the insane, and here the best treatment still seemed to be pyrogen therapy, especially by the induction of malaria. Finally, he wished to refer to the second group of remedies, those which stimulated the tissues to reaction; he would like to stress the importance of the patient's metabolism in combating the disease, and he had found the administration of thyroid gland to be most beneficial in provoking tissue activity.

Sir JAMES DUNDAS-GRANT said that he still believed inunctions of mercury to have a definite value.

Dr. ANTHONY FEILING agreed that neuro-recurrences were more frequent in those who had been treated by courses of arsenobenzene followed by mercury. He had recently been using bismuth in cases of tabes, almost to the exclusion of arsenobenzene preparations. General paralysis of the insane was so resistant to ordinary remedies that malaria still offered the best chance of improvement.

Dr. COTTON spoke of a series of cases of cardio-vascular syphilis which he had treated with intravenous injections of novarsenobillon and with continuous mercury and potassium iodide. On comparison of his results with those in a series of untreated cases he had found the difference in the mortality rate to be not more than 10 per cent.

Dr. W. R. RUSSELL spoke of several methods, other than malarial infection, of producing pyrexia in general paralysis of the insane. These had not succeeded in obtaining a temperature of more than 100° F. for four or five days, and it had been decided that malaria was more reliable.

Dr. RUSSELL BRAIN had found the use of malarial therapy valuable in the treatment of tabes, though he would not, of course, advise it in the cases which responded to ordinary antisyphilitic measures.

Dr. TREVES BARBER and Dr. CAWADIAS also spoke, and Colonel HARRISON replied.

TREATMENT OF LUNG ABSCESS.

AT a meeting of the Section of Medicine of the Royal Society of Medicine, on February 25th, with the president, Dr. R. A. YOUNG, in the chair, a discussion was held on the treatment of lung abscess.

Dr. F. G. CHANDLER, opening, said it was not proposed to discuss etiology or diagnosis, but the cause of lung abscess did throw light on treatment, and accurate localization was a preliminary to surgery. The possibility of a foreign body being present in the lung had always to be excluded by careful study of the history and by *x*-ray examination, with bronchoscopy if there was the slightest doubt. As regards accurate diagnosis, physical signs had to be looked for in cases of abscess of the lung, while great help was obtainable from radiological examination, especially by the lateral view. If no foreign body could be detected a patient with lung abscess should be treated first by medical means, for in many cases complete recovery was possible after removal of the contents of the abscess by coughing; in other cases medical treatment was useful while the abscess became localized. Such treatment comprised rest in bed; an attempt at postural drainage, which the speaker considered of doubtful value; inhalations; sedatives for the cough; and attention to all oral and nasal sepsis. Arsenic was useful in view of the frequency of spirochaetes in the pus of abscesses in the lung. The duration of medical treatment depended upon the urgency of the symptoms, the tendency to localization, and the degree of cough; deterioration in the general condition of the patient, and enlargement of the abscess as shown by *x* rays, indicated the need for surgery. Dr. Chandler then mentioned the value of lipiodol in diagnosis, and, passing on to the various methods of surgical treatment, he said he thought bronchoscopy of little value except where there was a foreign body present, or some definite obstruction to a bronchus. Artificial pneumothorax was useful for deep-seated abscess of the lung, but there were many dangers in this method, especially the risk of producing an empyema if the abscess was situated superficially. The operative treatment by drainage was especially suitable for the localized type of abscess, but it was of the greatest importance to make certain that the two layers of the pleura were adherent; stitching these layers together was useless, and the operation must be performed in two stages with an interval for pleural adhesions to develop if these were not already present. In cases where drainage did not completely cure the condition and a sinus persisted phrenic evulsion was valuable, while in chronic persistent cases thoracoplasty had to be considered. Dr. Chandler finally emphasized the importance of local anaesthesia in operations on lung abscess.

Mr. TUDOR EDWARDS stressed the value of accurate diagnosis, especially as regards the previous history, and the signs and symptoms. The symptoms were either intermittent or continuous, and if continuous the condition of bronchiectasis was simulated. X-ray examination was essential for diagnosis, both lateral and oblique views being valuable, while the fact that lipiodol did not enter the affected portion of lung helped in a difficult case. The speaker agreed that medical treatment should be given a good trial before there was resort to surgery, and he mentioned postural drainage and the exhibition of arsenic as being particularly advantageous. Artificial pneumothorax was useful only when the abscess was situated near the hilum of the lung, and in superficial cases the danger of septic pyopneumothorax was great. In all cases when medical measures failed external drainage was the method of choice, and it should be adopted when either the general or local condition of the patient was getting worse. Local anaesthesia was best, but in a nervous patient gas and oxygen might be used. The abscess should be previously emptied by postural drainage, and whether the operation comprised one or two stages would depend upon the state of the pleura. The two layers must be adherent; if this was not the case the wound must be packed with iodoform gauze for seven to ten days before the pleura was incised. Healing might take several months; in basal abscesses particularly phrenic evulsion often hastened a cure. Thoracoplasty was not necessary if adequate treatment was given in the early stages, and this operation was reserved for patients where this had not been the case. Lobectomy by means of the cutting diathermy was useful when there were multiple small abscesses present. Mr. Tudor Edwards added that his mortality rate for forty-five cases, excluding malignant disease, was 17.7 per cent.

Dr. L. S. T. BURRELL said that the treatment of lung abscess depended upon its position and character; it should aim essentially at securing drainage of the pus. If this was taking place through a bronchus recovery could be expected, but cases were frequently met with in which this drainage was insufficient, and the retained pus seemed to soak into a large area of lung. He thought it ought to be possible to take steps to prevent this, and in early cases where bronchial drainage seemed ineffective he recommended artificial pneumothorax. There were many theoretical objections to this, but the success of the treatment in certain cases was remarkable. Even if pyothorax occurred the patients might still recover, and Dr. Burrell believed that artificial pneumothorax did prevent the spread of pus in the lung. In later cases of chronic abscess surgical measures were necessary, and he thought that in the future the ideal treatment would be lobectomy of the affected portion of the lung.

Mr. J. E. H. ROBERTS remarked that the discussion had been mostly concerned with one type of lung abscess which gave good results; pulmonary suppuration was, however, of many types. He instanced frank gangrene of the lung, localized abscess in a mass of gangrene; multiple abscesses in a spongy lung; a large single abscess lined by granulation tissue, or, more rarely, by stratified squamous epithelium, interlobar empyema; bronchiectatic abscess cavities, bronchiectasis; and abscesses forming behind some bronchial obstruction. When compiling statistics it was very important to be quite clear which type of abscess was meant. He agreed about the value of *x* rays in diagnosis, and he mentioned cases where radiological examination had been the only means of diagnosis. Exploratory puncture was dangerous in lung abscess, and it was very difficult to determine when medical treatment had continued sufficiently long. With regard to operative procedures, Mr. Roberts emphasized the necessity of obtaining access to a greater area of lung than that provided by removal of a portion of one rib; two or three ribs might have to be dealt with.

Mr. HERBERT TILLEY said he was interested in the subject of lung abscess because of the risk of its following operations upon the upper air passages. He thought this was especially likely if such operations were performed in the sitting up position, as was common in America, where pulmonary complications of tonsillectomy, for example, occurred more frequently than in this country. He had recently visited Chevalier Jackson's clinic, and had been impressed with the value of bronchoscopy. As performed in that clinic this method seemed comparatively simple; local anaesthesia was used for older people, but children walked quite happily to the operating theatre for the passage of a bronchoscope without any anaesthesia at all. Aspiration of lung abscesses was carried out two or three times a week in this way, and argyrol drops were sometimes introduced. Mr. Tilley thought the method should be seriously considered in cases of lung abscess.

Dr. H. V. MORLOCK described a series of thirty cases of lung abscess treated at Victoria Park Hospital. Of eleven patients treated medically nine had recovered completely, while two had died. He thought that, generally speaking, the surgeon should be called in after about eight to ten weeks, but earlier if the patient's condition was deteriorating. Five patients had been treated with artificial pneumothorax with four recoveries, despite pyothorax in two instances. Other cases had been treated by drainage, or,

as in two instances, with thoracoplasty. Dr. W. E. LLOYD mentioned the frequency of abscesses in the right lung as proof of the danger of inhaling foreign material at operation. In elderly people the possibility of lung abscess secondary to malignant disease had to be remembered. He mentioned cases where fetor of the breath had been the only sign.

The PRESIDENT thought pulmonary suppuration was probably commoner than was generally realized, because so many patients recovered spontaneously. Fetor of the breath was an important sign, and abscesses were often discovered only on *x*-ray examination. He thought it important for the profession and the public to realize that thoracic surgery was now in the position that abdominal surgery had occupied a generation ago; if there was careful team work there should be great possibilities ahead. The tendency was to operate for intrathoracic conditions at a much earlier stage than heretofore.

MYELOPATHIC ALBUMOSURIA.

A MEETING of the Section of Medicine of the Royal Academy of Medicine in Ireland was held in the Royal College of Physicians on February 7th, with the president, Dr. ROWLETTE, in the chair. A case of myelopathic albumosuria was reported jointly by Drs. A. R. Parsons, Garratt Hardman, J. T. Wigham, and J. Lait.

Dr. PARSONS recounted the history of the patient, who had been under his charge. The recognition of Bence-Jones "protein" was discussed, and the difficulties in detecting it in urine were elucidated. Dr. Parsons dealt with the history of the disease, and commented on the fact that it appeared to be rare in Ireland; the first Irish case had been reported as recently as ten years previously, and the present case was only the fourth on record. Drs. WIGHAM and LAIT described the post-mortem findings. An interesting feature was the presence of bilateral fibrotic pulmonary tuberculosis. This was first detected by *x*-ray examination, which also showed that the bony growth on the left third rib consisted of a localized rarefaction and expansion. Radiograms of the spinal column showed that all the vertebrae were slightly more translucent than normal, indicating a general decalcification of bone. Dr. T. GARRATT HARDMAN described his radiological findings, which emphasized the importance of supplying the radiologist with full information about any case examined radiologically. In this particular instance the detection of the lung tuberculosis led to a tentative diagnosis of tuberculosis of the rib, the peculiar features of the urine not having been mentioned. Dr. Hardman said that Baetjer, radiologist to the Johns Hopkins Hospital, had described the appearance of myeloma in bone as follows: "It is a multiple lesion, and the bones are pierced by small focal spots of destruction. It does not expand or destroy the cortex. There is marked rarefaction of the bones, the cortex may be thinned out, pathological fractures are common. It is very difficult to make a diagnosis from the roentgenogram alone." The speaker added that the *x*-ray appearance in this case did not conform to Baetjer's description, inasmuch as definite expansion of the bone was present.

Dr. G. E. NESBITT discussed the difficulties in detecting the Bence-Jones substance in routine examination of urine. Dr. J. SPEARES referred to his case, the first described in Ireland, and emphasized two points of diagnosis—the weakness of the patient, and the tenderness, especially upon percussion, over the bones. He asked Dr. Parsons about the condition of the patient's tongue. In his own case the patient had been unable to protrude it from the mouth, and it looked almost like the textbook "wooden tongue." Dr. G. BEWLEY referred to the case described previously by him. If urine testing was performed carefully it was not easy to miss the Bence-Jones protein, since the low temperature at which precipitation began was most striking. Dr. A. GOFF described the illness of his patient, the third case of the triad referred to by Dr. Parsons. The illness had come on suddenly, and drenching sweats which stiffened linen were a striking feature. There was also extreme weakness, which had improved most remarkably with the onset of the warm weather. He had undertaken rough estimations of the amount of "albumose" in the urine, and had found that towards the end of the illness the amount was nearly doubled.

Dr. PARSONS, replying, said that in his case the tongue was quite normal. He confirmed Dr. Bewley's opinion about the case of recognizing the abnormal substance in the urine. As a contrast to Dr. Goff's case the duration was only eight weeks.

Clinical Cases.

Dr. P. MACCARVILL showed a case of xanthoma tuberosum multiplex in a woman aged 39. The eruption had appeared rapidly in the last nine months or so, and was accompanied by jaundice. The upper part of the abdomen contained a large mass which, although it extended to the left costal margin, Dr. MacCarvill believed was an enlarged liver. There was little noteworthy in the previous history, with the exception of eight pregnancies during the last twelve years. A full clinical examination still left the cause of the illness in uncertainty. The speaker inclined to the opinion that the icterus and enlarged liver were the result of multiple xanthomatous nodules. Finally he discussed the condition in general, and drew attention to the importance of distinguishing it from the very common xanthoma palpebrarum.

Dr. J. SPEARES showed a case of persistent pneumothorax where diagnosis had been difficult. A girl, aged 8, had been seen by him first in September, 1929; the only complaints were shortness of breath while running about, and a cough for seven years. Clinical examination, helped by *x*-ray investigation, revealed a large unilateral pneumothorax, or possibly an air-containing cavity. Dr. Speares dealt with the rarity of such a picture, and the difficulty in explaining how it came about, discussing the differential diagnosis between pneumothorax and a large air-containing cavity, and referring to the possibility of a bronchial fistula. He said it was important to keep in view the fact that the condition seemed to be causing but slight trouble. He therefore deprecated the use of a puncture needle or lipiodol injection as diagnostic procedures which were not entirely devoid of risk. In such a case as this any diagnostic method likely to inflict shock should not be used without a clear notion of what gain was to be expected from it.

Dr. R. STUMPF showed a case of lupus vulgaris treated by radiotherapy and the Gerson diet, describing this method of diet and the indications for its use. The case was of very long standing, but under treatment by *x* rays and the Gerson diet it proceeded to heal with a rapidity which was quite unusual. A notable feature was the absence of scarring.

MATERNAL MORTALITY.

AT a meeting of the Newcastle-upon-Tyne and Northern Counties Medical Society on January 9th, with Dr. H. S. BROWN, the president, in the chair, Dr. E. FARQUHAR MURRAY opened a discussion on maternal mortality.

Dr. Farquhar Murray stated that 3,596 maternal deaths had occurred in Britain during 1928, nearly half the number being due to sepsis. The figures for Northumberland, Newcastle, and Durham were 29, 22, and 102 respectively; 52 deaths had occurred at the Princess Mary Maternity Hospital during 1928, half of the number being primiparae. About sixty women were sent into the maternity hospital by doctors each month on account of complications. The amount of ill health associated with maternity was enormous, but no reliable estimate could be made. Many deaths and much of the ill health were due to an absence or insufficiency of medical supervision and nursing. The present maternity service, while excellent in parts, was in others hopelessly primitive. The medical and nursing supervision must be intensified and organized if real improvement was to be obtained. The provision of maternity clinics in industrial areas would place examination facilities at the disposal of the doctors, linking them with the

midwives and maternity hospital, and make for better supervision and efficiency. Provision should be made for expert assistance to be available in necessitous cases.

Mr. H. HARVEY EVERS emphasized the fundamental importance of ante-natal care, co-ordinated with intra-partum and post-natal supervision. Puerperal sepsis, the toxaemias, and the haemorrhages, as the chief clinical causes of maternal mortality, were discussed in his paper. The outstanding features of each were briefly mentioned, and the salient points of prophylactic methods were clearly indicated. The present tendency to expect too much from ante-natal care alone was deplored; this care must be regarded as an adjunct to, and not a substitute for, good practical midwifery. The general conditions of domestic midwifery and the facilities must be improved if maternal mortality was to be materially reduced.

Dr. HAROLD KERR devoted his short paper to a consideration of maternal mortality from the more purely public health point of view. A short statistical review of maternal mortality in Newcastle-upon-Tyne was submitted, and some of the associated public health problems were indicated. Dr. L. M. WEEKS presented the attitude of the general practitioner in industrial as well as in purely private practice. He laid particular stress upon the value of good nursing, good ante-natal care, and readily accessible assistance from specialists. Dr. GEORGE STEPHENSON, taking the pathologist's standpoint, contributed an analysis of the statistics of maternal deaths in the Royal Victoria Infirmary, and emphasized the overwhelming importance of sepsis.

HORMONES CONTROLLING REPRODUCTION.

AT a meeting of the Eugenics Society held in the rooms of the Royal Society, Burlington House, on February 26th, with Professor E. W. MACBRIDE in the chair, Dr. B. P. WEISNER, of the Animal Breeding Research Department, Edinburgh, delivered an address on the hormones controlling reproduction.

He would not, said the lecturer, deal with hormones exercising only an indirect effect on reproduction—for example, the secretion of the thyroid gland—his address was concerned exclusively with those hormones that influenced reproduction directly: and in discussing this subject he would consider not only the hormones themselves and the differences between them, but the way in which the reaction of the genital system to hormones varied from species to species. The conditions in the male were relatively simple: there had been a continuous evolution of knowledge through the work of Berthold, Brown-Séquard, Nussbaum, and Steinach, culminating in Koch's recent success in extracting the testicular hormone in highly concentrated form. This substance, it had been shown, exercised a powerful action in controlling and promoting the production of male sexual characters, inciting the mating instinct, activating the prostate and vesiculae seminales in immature animals, and reactivating them in castrates. Furthermore, this secretion activated that function of the epididymis whereby it maintained spermatozoa in a viable state. Differences in the viability of sperms, and thus indirectly of reproductive capacity, were in some measure due to differences in the supply of testicular hormone. This hormone, apparently, controlled the development of the typical testicular structure, and by its means embryonic female gonad could be transformed into a testoid organ. In female mammals, continued the lecturer, the conditions were rather more complicated: in these the sex cycle dominated genital function, and there were great differences between species and species. In the cycle of most lower mammals there were two completely differentiated phases: the sexual and the reproductive. During the former the complex conditions for fertilization were created, and the mating reflex, the so-called sex instinct, could be incited. During the reproductive phase the uterus provided the conditions for the nidation of the egg, and later the maternal reflexes could be incited. The sexual phase was set into activity by means of oestrin: the reproductive phase by a hormone of the corpus luteum. The presence of these hormones within an extract could be ascertained by injecting it into immature mice and then examining their vaginal epithelium. Oestrin produced cornification; the luteal hormone (kythin) produced mucification. The mucified vaginal epithelium, unlike the cornified epithelium, did not consist of flat keratin scales without staining nuclei, but of mucous cells each having a darkly staining nucleus. Kythin was the pregnancy hormone: its injection prolonged pregnancy and prevented oestrus. The injection of oestrin, on the other hand, interrupted pregnancy or prevented it. In lower vertebrates the uterus and vagina reacted apparently alternatively to the two hormones in question. Kythin, stated Dr. Weisner, fulfilled an important biological function; it was secreted independently of fertilization, and, whether fertilization took place or not, it induced the conditions of pregnancy. Thus the germ plasm, playing no part itself in preparing the uterus, was relieved of somatic functions. On the other hand, in the absence of fertilization, the preparation of the uterus led to the occurrence of pseudo-pregnancy, the price paid for the relief of the germ plasm, and an integral part of all sex cycles in all female mammals. In human beings pseudo-pregnancy was represented by the pre-menstrual phase, the menstruation representing a pseudo-birth. In the menstrual cycle, however, there was no sexual phase, the whole cycle being equivalent to the reproduction phase of the lower mammals. But while in the latter the reactions of the genital system to the ovarian hormones occurred in alternation, in the menstrual monophasic cycle they were synchronous and complementary. In human beings both ovarian hormones were secreted at the same time. The ovary did not function independently or only according to its own rhythm. Transplantation of an immature ovary in an ovarectomized mature female led to immediate maturation of the graft; transplantation of a senile ovary into a mature female, to recurrence within it of follicular maturation. Such experiments indicated the presence of extra-ovarian factors regulating and conditioning ovarian function. These factors, said Dr. Weisner, were located in the anterior lobe of the pituitary; not merely one sex hormone governing the function of the ovary, but two distinct factors—an oestrogenic hormone, which induced follicular maturation and secretion of oestrin, and a kythogenic hormone, which induced the formation of kythin, and thus led to the development of pregnancy conditions. The presence of oestrogenic hormone in extracts could be recognized by the appearance of vaginal cornification on their injection into immature mice; the presence of kythogenic hormone by the appearance of mucification. These hormones were obviously antagonistic in animals having a bi-phasic sex cycle, but synergic in monophasic animals. The testicle also depended for its integrity on the supply of anterior pituitary secretions. In rats, ageing of the testicle could be repaired in a few days by injecting oestrogenic hormone, this treatment had brought about not only complete restoration of spermatogenesis, after its senile disappearance had been observed, but reactivation of accessory glands. Just as other hormones than those secreted by the sex glands influenced reproduction, so the effects of the hormones of the sex glands were not restricted to the genital functions. They had a marked influence on the metabolism and the spontaneous activities of experimental animals, and thus, concluded the lecturer, the control of reproductive hormones implied much more than the control of reproduction.

THE first annual general meeting of the North of England Dermatological Society was held in Manchester on February 7th, with Dr. SAVATARD, the president, in the chair. The following officers were appointed for 1930: president, Rupert Hallam; vice-presidents, G. H. Lancashire and R. Stopford Taylor; honorary secretary, P. Brooke Mumford; other members of council, W. Dyson, J. T. Ingram, and E. F. Skinner; editor, L. Savatard. The following meetings were arranged: March 14th, at Sheffield; May 9th, at Liverpool; June 13th, at Leeds; October 10th, at Manchester. The business meeting was preceded by a demonstration of cases and followed by a dinner at Parker's Restaurant.

Reviews.

THE PATIENT AND THE DISEASE.

THAT in the practice of medicine the doctor should treat the patient rather than the disease is an exhortation of highly respectable parentage and standing. A necessary preliminary to this achievement is the ability to recognize and estimate the qualities which give to the patient the mark of a distinctive personality, and Professor GEORGE DRAPER'S *Disease and the Man*[1] may be briefly described as a contribution directed to this end. Its scope is the quality of the patient as well as the nature of the disease, and it undertakes to show that there are features in human constitutions which incline one group of persons in one disease direction and other groups in other disease directions. Thus the purpose of the book is a study of personality and of the relation of this to diagnosis and to disease incidence; while at the same time an attempt is made to conduct the necessary studies by methods which in their results approach in accuracy those of the laboratory. The enterprise is certainly a very engaging one; and it is supported by knowledge gathered over a wide area, by sound reasoning, and by practical clinical observations collected in a clinic specially organized for the purpose. Hence, while individual chapters deal with genetics, morphology, endocrine function, anthropology, sex, and psychology, these are in turn treated as avenues which converge to a common centre, where the patient in all his variety is to meet the physician in all his completeness.

Though very different in much of its subject-matter from other guides to practice, Professor Draper's book is essentially a study of clinical medicine, with the emphasis on the patient rather than on the disease; and the plan of examination is designed to detect and display, not merely anatomical structure (normal or abnormal) and functional activities (physiological or pathological) but the total personality of the patient. The proposed plan of clinical investigation is based upon the suggestion that the clinical portrait of the individual may be spread across the four panels of a screen, each panel carrying a separate portion of the complete picture. The first panel represents morphological character, the second physiological, the third immunological, and the fourth psychological. When all these are known and appreciated the patient is known, and included in this knowledge may be a recognition of his individual disease proclivities. Indeed, the claim is made that an anthropological classification may be arranged on a basis of disease potentiality as this can be determined by estimation of the four panels which together display the facts necessary to decide to what group the individual belongs. Further, there is found by experience that though details vary and the lines are not rigid ones, some measure of interrelation exists between the sectional pictures, so that where one panel is known a shrewd guess may be made as to the kind of facts which will be found in some of the other sections of the complete picture. In this way are worked out various types of "races," each having a more or less clearly defined morphological and psychological pattern, and each, as shown by collected observations, meaning a proclivity to a particular pathological condition such as gastric ulcer, pernicious anaemia, and so on. This scheme, as bluntly stated here, may seem to have a somewhat fantastic or manufactured quality, but the reader of Professor Draper's book will certainly not accept any such view. Even if he does not go the whole way with the argument he can hardly refuse a large part of the journey, and the travelling is as pleasant as it is interesting.

As Professor Draper views the situation, modern medicine suffers from an unfortunate cleavage between mind and body, and while the physical or mechanistic view of diagnosis and treatment is recognized the facts of the psychological "panel" are largely neglected and unappreciated. The emotional factor contributed by the patient is left out of court, and the clinical picture is in corresponding degree incomplete, for in every state of bodily suffering of whatever kind or degree this factor is in greater or less proportion included. The plea, therefore, is that a psychological estimate and judgement should be included as a necessary element in the examination of each patient. The physicians of an older school had their "general impressions" about patients and took these as important factors in prognosis and treatment, and even in diagnosis. In recent years many developments of knowledge in regard to the agencies which act upon man from the outside have occurred, and with attention turned in this direction the personality of the patient and the quality of his individual reactions to environmental influences have received inadequate consideration. There are signs of a reaction to the older tradition, this, however, being made more exact by associating with it methods of measurement. As in other reactions, there is here a risk of a good cause being qualified by the excesses of its advocates, and the author is careful to point out that overemphasis of the psychological aspect of physical disease is just as dangerous as its complete exclusion. Towards the establishment of a reasonable relation and proportion of the two factors his book renders practical service, and it deserves the careful study of all clinicians.

[1] *Disease and the Man.* By George Draper, M.D. Anglo-French Library of Medical and Biological Science. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1930. (5½ × 8¼, pp. six + 270; illustrated. 12s. 6d. net.)

MEDICAL ENTOMOLOGY.

WE have received for review the first of a series of four books on veterinary and medical entomology, written by Professor W. S. PATTON and various collaborators—in this instance Dr. ALWEN EVANS. The subsequent parts will be devoted to a consideration of entomology as applied to public health, to tropical hygiene, and to veterinary science. The present part deals with medical entomology[2] as required for tropical medicine.

The plan of the book is novel—startlingly so. It is based on the course for the diploma in tropical medicine as given at the Liverpool School. This course consists of twenty-eight meetings—each comprising lecture, laboratory work, and demonstrations. The volume is divided into chapters to correspond with these meetings, and full details about their conduct are given. They commence with the actual notes of the lecturer, complete even to such reminders as "*Briefly describe a typical case,*" "*Treatment and prophylaxis briefly described.*" These notes are followed by the subject-matter which accompanies the demonstration specimens—and this also includes such minutiae as "*Preserved in alcohol in a tube,*" "*Please do* not move the slide." and so on. Each specimen is illustrated, and most of the illustrations are excellent. Interspersed between these demonstration notes are pages of explanatory text. Each section concludes with an indication of what is required for examination purposes and what may with safety be forgotten.

Now a textbook of medical entomology should fulfil one of two functions—either instruct the elementary student or provide the advanced worker with detailed information. The system on which this book is based definitely limits its use to students at the Liverpool School. The minute instructions which no doubt render it invaluable to them are of little use to workers elsewhere, and produce a feeling of irritation which does much to discount the many other invaluable features in the book. (In passing, it may be remarked that a similar effect is caused by the continuous use of the old astrological and zoological signs to signify sex instead of spelling males and females in full.) The arrangement of the book to accompany a definite series of lectures and demonstrations makes it difficult to use it as a work of reference. This is doubly unfortunate as it is full of information, much of which is not obtainable elsewhere—the chapters on the myiasis-producing flies, for example, are unique. There are hundreds of excellent illustrations, mostly original, which can be found in no other publication, and which in themselves are well worth the modest pound asked for the whole book.

There are no good modern textbooks of medical entomology available in the English language. The present

[2] *Insects, Ticks, Mites, and Venomous Animals of Veterinary Importance, Part I: Medical.* By Walter Scott Patton, M.B., Ch.B.Ed., F.E.S., and Alwen M. Evans, D.Sc. To be obtained from Miss M. Braun, *Department of Entomology, Liverpool School of Tropical Medicine, Pembroke Place, Liverpool.* 1929. (Cr. 4to, pp. x + 785; 374 figures, 60 plates, 3 maps. 20s. post paid.)

volume contains more than enough excellent material to provide such a textbook. But its arrangement, as we have already indicated, is such as to limit its practical use to Liverpool students; while its bulk and wealth of intricate detail, which should render it invaluable as a volume of reference, are such that the student will be either swamped or driven to give to entomology an altogether disproportionate share of his time in the D.T.M. curriculum. The price of the book, however, is so low that even with these disadvantages of arrangement it is really good value, and it is well worthy of a place in every tropical library.

PRACTICAL MAMMALIAN PHYSIOLOGY.

"A NUMBER of facts fundamental to physiology can be seen by the student very readily and appropriately in the frog. But other facts there are, of great value and interest especially to the future practitioner of medicine, which can be better displayed and more easily obtained in the mammalian preparation." Not many will dissent from this observation with which Sir CHARLES SHERRINGTON introduced the first edition of his course of practical exercises in *Mammalian Physiology*.[1] After ten years a second edition of this admirable book has been called for. In its preparation the senior author has shared the labour of revision with his colleague Dr. E. G. T. LIDDELL. To those familiar with the book it is necessary only to say that revision has been restricted chiefly to matters of detail, only one new exercise having been added. If there be others who, charged with the instruction of classes in physiology or engaged in experimental work, are yet unfamiliar with this book, the occasion of a new edition is an opportunity for introducing to them a laboratory companion which should prove of great service. Some twenty-two exercises are described in full detail and admirably illustrated. Many are further illuminated by neat historical annotations elucidating the origin of the observations and their place in physiological thought. The price is not excessive for so elegant and well illustrated a production.

The course outlined in the above-mentioned book is too comprehensive for the usual medical curriculum. Its service is that of a store from which the teacher may make his choice for student exercise or demonstration. Opportunity may therefore be taken of drawing attention to a smaller, less ambitious—and withal less expensive—book which has just appeared. This is *An Introduction to Practical Mammalian Physiology*,[2] by Professor SWALE VINCENT and Dr. SAMSON WRIGHT. Its aim is to present a selected practical course in the subject, to which medical schools could introduce their classes without serious claims upon time or upon expensive apparatus. The course offered is well designed and is described in a manner which should make it a popular student's laboratory manual.

THE OPIUM PROBLEM IN INDIA.

Narcotics in India and South Asia[3] is the title of a booklet published by Williams and Norgate, which contains the result of investigations made during 1927–28 by Mr. H. G. ALEXANDER. The author is lecturer on international relations at Woodbrooke, Birmingham, and his Asiatic tour was made possible by a travelling fellowship awarded to him by the Selly Oak Colleges. Mr. Alexander's father was the well-known secretary to the Anti-Opium Society, which waged successful warfare on the Indo-Chinese trade in the drug, and he took an active part in furnishing evidence to the Royal Commission of 1894–95.

Mr. Alexander endeavoured to divest himself of previous prejudices, and to pursue his investigations in British India, the Native States, Burma, Malaya, and Java impartially and dispassionately. He inclines to the view that undue emphasis may have been laid by reformers on the admitted evils of opium smoking and opium eating, while paying too little attention to "manufactured drugs, whether derived from the opium poppy or the coca leaf, which are increasingly used all over the world for purely vicious purposes." Mr. Alexander accepts the view that opium is not to be regarded as a prophylactic against malaria, as the Royal Commission had maintained, and he condemns the too prevalent practice of "doping" babies with the drug. At the Ghazipur opium factory of the Government it appears that, besides preparing excise opium for Indian consumption and smoking opium for export, medicinal opium is there manufactured for English use, while from contraband seizures of opium morphine was extracted, and to the extent of thousands of pounds was, until March, 1928, consigned to London.

While thinking that the Indian Government might be "getting an overdose of blame," Mr. Alexander dwells on its contradictory policy of "taking measures whose avowed intention is to decrease consumption while its agents are trying to push sales in order to increase revenue," and he thinks that the Government policy of "maximum revenue with minimum consumption" inevitably "increases the reluctance of the Government to adopt a policy of honest restriction." The belief that India is being swamped by opium smuggled in from China is disputed by Mr. Alexander, who holds that such illicit commerce proceeds from Rajputana or from Persia. Since the export of Indian opium by the Government to China was stopped large stocks of Malwa opium have accumulated in Rajputana, and from this source, it is alleged, a stream of contraband opium finds its way into British India and to seaport towns. Assam, Berar, and Orissa, and most of the great cities, are "black spots" in the matter of excessive consumption of opium. Mr. Alexander is in agreement with some eminent pharmacologists that opium smoking is not the most harmful method of self-administration of the drug, though the official view has hitherto been that it is a pernicious and degrading vice. He concludes that neither opium smoking nor opium eating calls for the attention of Western reformers so much as the export to the East of manufactured habit-forming drugs, such as morphine and cocaine, and spirits, since "so long as we go to the East with these things in one hand, Chinese and Indians and Malays are not likely to have much use for programmes of social reform that we carry in the other."

The booklet is well worthy of perusal by any student of the opium problem, especially in the light of the recent discussions of the Advisory Committee of the League of Nations at Geneva.

THE FEMALE SEX HORMONE.

TWO RECENT MONOGRAPHS.

KNOWLEDGE about sex hormones has developed in a curiously irregular fashion: its beginnings date back to the time when prehistoric man discovered the elementary fact that removal of the sex glands modifies the growth of the body; the possibility of its scientific application was first exploited when Brown-Séquard administered orchitic extracts with a view to producing rejuvenation. Whereas, however, knowledge about sex hormones is more ancient than that of any other branch of endocrinology, between 1889 and 1920 the latter strode forward, and fruitful studies were made of other hormones, while knowledge of the sex hormones remained practically at a standstill. Thus it may be said that about ten years ago the experimental and observational data concerning the internal secretions of the sex glands compared unfavourably in amount with those that had been acquired in most other fields of endocrinology; since then, however, knowledge of the female sex hormones has advanced considerably; accurate methods have been devised for their identification and assay, and intensive research, directed upon the problems they present, has revealed a system of hormonic control of remarkable complexity and interest.

Unfortunately, the mass of work that has been done on the subject illustrates in a striking manner one of the main difficulties in the study of the data of modern biological science. The sheer bulk of the literature makes its mastery almost a full-time occupation. As, moreover,

the technique of research is difficult and results are worthless unless a rigidly accurate technique has been maintained, the literature is of varying value, and only those familiar with the experimental methods of endocrinology can separate the wheat from the chaff. In these circumstances only the specialist would be advised to follow original literature; for all others the only useful mode of approach is by way of authoritative and critical monographs. Of these latter, two may be specially commended: *The Internal Secretions of the Ovary*,[1] by Dr. A. S. Parkes (chosen by the new editors of Monographs on Physiology as their first production, since the death of Professor Ernest Starling), and *The Female Sex Hormone*,[2] by Dr. R. T. Frank. Both authors have made important contributions to present-day knowledge of endocrinology, and this fact alone lends special interest to their monographs.

Dr. Frank's work is divided into two parts: the first concerned with the biological, pharmacological, and chemical aspects of the subject; the second with the clinical investigations and results. The author, having reviewed the work done during the last decade, summarizes his own views on the many controversial problems that have arisen, stating the general conclusion that the existence of at least two sex hormones is well established. The female sex hormone, known as oestrin, menformon, and by a host of other scientific and trade names, and occurring in the follicular fluid and placenta, and in the blood and urine of pregnant patients, is, in his view, an anabolic factor which produces all the growth phenomena in the Müllerian tissue and in the breast, the type of phenomena produced depending on the amount employed and the duration of its action. This hormone occurs also in small quantities in all sorts of unlikely material—for example, yeast, many plants, male urine, bile, and the testis; some occurs in corpus luteum, which, however, contains another hormone that inhibits ovulation. The difficulties attending quantitative estimations of female sex hormone are indicated by the fact that Frank and his co-workers rarely found more than 200–300 mouse units per litre in the urine of pregnant women, whereas Continental authors, using the same technique, mention figures of 1,000–7,000 mouse units per litre. In the second part of his work Frank describes the method for estimating the amount of female sex hormone in the blood and urine; he presents clinical evidence to the effect that hypo- and hyper-function of the ovaries can be detected in certain cases by means of a blood test, and shows that this test is of service in the diagnosis of pregnancy. Of special interest is a chapter devoted to the pharmacology of ovarian extracts.

"I have," says Dr. Frank, "repeatedly put myself on record as entirely sceptical concerning the effect of desiccated, unconcentrated ovarian preparations. . . . The effects on the basal metabolism of oophorin and similar desiccated ovarian powders have never given uniform results and have not stood the test of careful scrutiny and repetition. . . . I have, during a number of years, tested the marketed preparations biologically, and found them, one and all, wanting in efficacy."

Similarly he tested the biological activity of a number of commercial extracts of the female sex hormone, which, according to the manufacturers, had been biologically standardized; his tests showed an activity varying from 0 to 30 per cent. of the amount claimed. "These titrations," he says, "are extremely disappointing, showing that even if the material left the hands of the manufacturer with the amounts of mouse or rat units labelled, deterioration rapidly destroys most of the activity and makes the clinical use illusory." He does not discuss the unassayed preparations, but the results obtained with those alleged to have been standardized indicate how unlikely it is that these would possess any activity.

The present position of female sex hormone therapy Frank sums up as follows:

"Assay and biological standardization of the water-soluble commercial extracts now placed upon the market show a woeful lack of potency and rapid deterioration of the products. Unpleasant local reactions may arise at the site of injection. The prices of these pharmaceutical preparations are prohibitive. Consequently I warn against their general use until better products are at our disposal."

Of the future, however, he writes more optimistically:

"If, as is to be hoped for, the future places a concentrated and stable female sex hormone in our hands, this powerful drug will enable us to produce transient stimulation of the uterus. Upon the withdrawal of the drug a single menstruation should occur, but it must not be forgotten that the ovaries are not stimulated by the female sex hormone. The possession of a potent aqueous corpus luteum extract may enable us to control too frequent and too prolonged menstruation. Again this effect may be expected to be transient. On the other hand, an active anterior lobe pituitary preparation should enable us, when it has been successfully elaborated, to actually stimulate the ovaries to increased function and activity."

Some idea of the scope of Dr. Parkes's monograph is indicated by the bibliography, which contains no fewer than 661 references to English, American, and Continental literature. Parkes, indeed, has assimilated completely present-day knowledge about the ovary, and the well-digested product he presents in a monograph of only 206 pages. The early chapters on the various types of oestrous cycle in animals, and of anatomy, form the best possible introduction to the study of a subject in which animal experiments have played a vital part in the building up of sound working hypotheses. The differences between the various kinds of animals are clearly set out, and the similarities well correlated; in this way the results of different workers, which appear at first sight to be contradictory, are shown in many cases to represent different types of reaction peculiar to particular species.

The comprehensive review of the subject given in the first part of the book forms an excellent introduction to the detailed study of the ovarian hormones. The function of the corpus luteum and of the pituitary, and their interrelationship with the oestrus hormone, are all fully discussed; and a chapter on parturition, and the way in which it is influenced by the internal secretions of the ovary, summarizes well the present-day knowledge of some at least of the factors involved in the onset of labour. A large amount of space is devoted to the oestrus-producing hormone, and from the historical survey of the work in this field we realize the difficulties that have had to be overcome in producing active extracts of this substance. Advances have come largely from improvements in methods of preparation, but perhaps even more from improved methods of physiological assay, and the stages by which our knowledge has advanced are clearly indicated, and the methods of testing the potency of extracts, and of their standardization, are fully explained.

Laboratory investigation of the function of ovarian hormones has advanced greatly during recent years, and the author does not hesitate to draw definite conclusions from sound experimental evidence in animals; but he is extremely cautious in the application of these results to clinical problems, and, indeed, there appears to have been but little orderly clinical research into the action of ovarian extracts, in spite of the fact that their use is widespread. Partly owing to the difficulty of assessing the importance of functional changes in women, and partly on account of the irresponsible way in which these extracts are so often used, the day of rational therapy by these means has not yet come; but the very firm foundation laid by animal research will encourage us to look forward in the near future to a new and potent weapon for clinical therapeutics.

Both monographs—Parkes's *Internal Secretions of the Ovary*, for its admirable survey of present-day knowledge of the ovary as an endocrine organ, and Frank's *Female Sex Hormone*, for its cautious and critical review of female sex hormone therapy—deserve careful study alike from physiologists and clinicians. Interesting and important laboratory results have been obtained, but it is evident that their clinical application presents technical difficulties which have not yet been fully overcome. This fact must be stressed, because a new therapeutic agent of much potential importance has been discovered, and it will be a great misfortune if its value is obscured by the disappointment that will inevitably follow if it is extensively employed before these technical difficulties have been surmounted.

ENLARGED PROSTATE AND PROSTATECTOMY.

SECOND LETTSOMIAN LECTURE BY SIR JOHN THOMSON-WALKER.

THE second Lettsomian Lecture[1] was delivered by Sir John Thomson-Walker before the Medical Society of London on February 26th, with Mr. H. W. CARSON, past-president, in the chair.

Selection of Cases for Prostatectomy.

Sir JOHN THOMSON-WALKER said that in the selection of cases for prostatectomy the points to be considered were the prostate, the urinary organs, and the general condition of the patient. With regard to the first point, two conditions were to be considered: the fibrous prostate, and the malignant prostate. The term "fibrous prostate" had been adopted without any very careful definition of the pathology, and it included a number of conditions of varied pathology. Out of 44 prostates weighing 20 grams or less, which he had taken as representing this type of prostate, the result of microscopical examination was as follows: adenocarcinoma 1; adenoma with little change in stroma 14; adenoma with amyloid bodies 3; hyperplasia of the stroma 5; chronic prostatitis and fibrosis of stroma 14; and multiple small calculi 7. Another type of fibrous prostate not included in this list was the adenomatous prostate which had been subjected to such treatment as deep *x*-ray therapy, causing fibrosis of the stroma. Evidently, therefore, the surgical term "fibrous prostate" covered a number of different pathological conditions, such as adenomatous enlargement, chronic prostatitis, fibrosis of the stroma, and a form of early malignant growth which developed around the internal meatus. At the operation difficulty in enucleation was the principal feature. It might be impossible to remove the gland by enucleation, but by transvesicular dissection these prostates could be cleanly and thoroughly removed.

Of the malignant prostate there were two distinct clinical forms, which might be termed primary and secondary. In the primary malignant prostate the changes in the gland were cancerous from the outset; in the secondary the character was that of the ordinary enlarged prostate, and the malignant changes were engrafted. The proportion of primary malignant prostates to simple was about 1 to 6. Among 2,496 cases of enlargement of the prostate which he had seen in private practice, there were 347 cases of undoubted malignant growth (13.9 per cent.), as against 2,149 cases of simple enlargement.

The secondary malignant growth was a growth engrafted on a simple enlargement of the gland. These patients came to the surgeon with symptoms of simple enlargement, and rectal examination confirmed the diagnosis. The malignant growth might develop in one of three localities. It might infiltrate the base of the prostate in the neighbourhood of the internal meatus, in which position it was not discovered until operation. It might affect the periphery of the enlarged gland, in which case the examining finger recognized an enlarged prostate of elastic consistency with a firm area at one part. At the operation the enucleation proceeded smoothly except at this area, where the gland was tough and adherent; a leathery plaque was not infrequently left behind on the wall of the prostatic bed, and might be dissected away in the open operation after removal of the organ. Finally, the malignant change might develop in the substance of the enlarged prostate. In 521 cases in his private practice where a pathological report was obtained on a specimen removed by suprapubic prostatectomy, there were 96 cases in which areas of carcinoma were discovered. In these cases there had been no suspicion of malignancy before operation, and the operation was performed by enucleation in the belief that the prostate was the seat of a simple enlargement. He compared his own figures with those of other workers as follows:

	Cases.	Malignant.
Albarran and Hallé	169	14
Wade...	134	14
Jocelyn Swan	23	4
Thomson-Walker...	521	96

The prognosis in such cases was important and extremely interesting. He had endeavoured to trace the subsequent history of the 96 cases in his series, and found that it was as follows:

Died from other causes within a year	13
Not traced	17
Alive and without recurrence	41
Died without recurrence	23
Died with recurrence	2

Of the 64 cases known to have had no recurrence the following were the periods:

	Alive.	Dead.
1 to 5 years	6	9
5 to 10 years	20	8
10 to 17 years	15	6

Urinary Complications.

Of all the risks to which the sufferer from enlargement of the prostate was exposed, those connected with the urinary organs were the most common and most frequently fatal. These complications were, however, to a large extent amenable to treatment before operation; they consisted of renal inefficiency and sepsis. With the increasing obstruction of a large prostate and residual accumulation, the renal function became impaired and a well-known train of symptoms developed indicating a varying degree of uraemia. These clinical symptoms were invaluable in the diagnosis of renal inefficiency, but there were cases of serious impairment of renal function in which they were slight or absent.

For more than thirty years urinary surgeons had endeavoured to measure the renal function accurately by means of special tests, and of late years they had received most valuable assistance from the biochemist and physician. The form of renal inefficiency which resulted from urinary obstruction was that in which the nitrogenous products were excreted in diminishing quantities in the urine and were accumulated in the blood. It followed that the estimation of the activity of the kidney in the excretion of these nitrogenous bodies, together with the estimation of the nitrogenous bodies in the blood, furnished an indication of renal function. In a series of 274 cases of enlargement of the prostate in which prostatectomy or cystotomy was performed the figures for the urea concentration test were as follows:

Urea Concentration	Cases.	Died from Uraemia.
2 per cent. and over	194	0
1.8 to 2 per cent.	21	1
1.5 to 1.8 per cent.	34	3
1.5 per cent. and under	25	3

The particular interest of these figures was in the cases where a high urea concentration was obtained and the patient died from uraemia or a low urea concentration test was recorded and the patient nevertheless survived. In ten instances where the urea remained at 1.5 per cent. or under, the second stage of prostatectomy was performed and the patient survived. In nine cases where the concentration was at this same low level a single-stage prostatectomy was performed, the patients surviving. The conclusion to be drawn from these 274 cases was that there was no risk of uraemia following prostatectomy if the urea concentration figure was 2 per cent. or more, but there was a serious risk with a figure below 1.8 per cent., and still more so below 1.5 per cent. With extreme care it was possible to operate successfully even where the urea concentration was below 1.5 per cent. Such patients might recover when no complications, such as bronchitis, haemorrhage, or sepsis, were present.

[1] The report of the first lecture was published in the *British Medical Journal*, March 1st, p. 402.

The estimate of the urea content of the blood gave additional information with regard to the functional activity of the kidney. The normal urea content of the blood was 20 to 40 mg. per 100 c.cm., but such figures were too low in dealing with old men, and a blood urea of 50 mg. might be present without indicating serious impairment of renal function. The ultimate cause of the symptoms grouped under the term "uraemia" was not the accumulation of urea in the blood, but the production of a chemical body or bodies to which the accumulation of urea in the blood ran closely parallel. The parallel, however, was not always close enough to make the blood urea figure an absolutely reliable test of the uraemia. A very low protein diet might so reduce the blood urea as to make the observation worthless. It was possible also to have a very high blood urea without the patient being in any danger of uraemia. Further, an excessive protein diet might raise the blood urea content. In most cases, however, the urea content of the blood varied inversely to the percentage of urea secreted in the urea concentration test. The blood urea content was invaluable in watching the progress of a case where the bladder had been drained in chronic retention with serious renal inefficiency. It was not necessary for a successful prostatectomy that the renal function should be perfect, or even approximately perfect; a reduced renal function might be adequate for the operation. Laboratory figures of the renal function tests formed only one factor among many in estimating the prognosis of the operation.

Sepsis and the Cholesterol Test.

The lecturer passed to the consideration of sepsis in relation to enlarged prostate and prostatectomy. Infection might occur before the operation, might be introduced at the time of the operation, or might occur subsequently while the wound was still open. He was concerned for the moment with the first of these occurrences. The simpler cases were those in which the infection was confined to the bladder; these were sometimes complicated with epididymitis. In the more complicated cases involving pyelitis, pyelonephritis, and recurring attacks of fever, the patient eventually drifted into the condition known as urinary septicaemia. If the infection was moderate and there was no evidence of renal involvement, a few weeks' preparation by bladder washing, together with diuresis and the use of urinary antiseptics, would suffice as a preliminary to the removal of the prostate. Where the more severe grade of sepsis was present, prostatectomy would be necessary in two stages.

As for the selection of cases for prostatectomy where sepsis was present and had been treated, in the mild cases, in which the infection had been confined to the lower urinary tract, there was no difficulty, but when the infection had been severe the decision was less easy to make. When the sepsis had been confined to the bladder it generally cleared up pretty quickly as a result of drainage and constant irrigation. A method which promised greater accuracy with regard to prognosis was the estimation of the blood cholesterol. Cholesterol played an important but an ill-defined part in the process of immunity, and its amount in the blood was liable to be affected by many external factors, all of which were not fully recognized. It was known to be increased in arterio-sclerosis, in granular kidney, in other degenerative conditions of later life, in uraemia, especially where the red cells fell below 50 per cent. of the normal, and in malignant disease. It would seem that, on the average, the cholesterol tended to reach high figures where rapid healing was occurring, and remained low where the healing of the sepsis was delayed, but there were individual cases which completely upset the clinical application of these figures. The question the surgeon had to face in regard to such a test was whether he could make the decision as to operation from the figure of the cholesterol content of the blood. The lecturer's view was that he could not do so at the present time, and that much more careful work was required before this test of the resistance to sepsis was brought up to the level of reliability that the estimation of the urea content of the blood or the urea concentration test had reached in relation to renal inefficiency.

Circulatory Risks.

A large proportion of the patients who were submitted for prostatectomy showed signs of arterio-sclerosis; a few had valvular disease, and some had impairment of the myocardium. The degree of circulatory strain that was permissible in any given case must be decided by the physician and the anaesthetist. The first striking point in regard to the systolic blood pressure in cases submitted to prostatectomy was that a large number showed a low blood pressure, a considerable number a very low pressure. This was contrary to what one would expect from the age of the patient, and was certainly against the view that senile enlargement of the prostate was always accompanied by arterio-sclerosis. On the other hand, there were a number of cases where the systolic blood pressure was very high. With a very high blood pressure a large number of cases of serious haemorrhage would be expected, yet in 15 cases with a systolic pressure of over 200 only 2 showed severe post-operative haemorrhage, and in no case was there serious haemorrhage at the operation. In 20 cases with low blood pressure 4 were associated with severe haemorrhage at the operation and 2 with post-operative haemorrhage.

The occurrence of thrombosis in a proportion of cases where the blood pressure was very low and the patient was immobilized in bed for a period of time seemed almost inevitable. When a septic focus lay in close relation, practically in direct communication, with a plexus of veins, clotting became a certainty. The lower the blood pressure the greater the probability of thrombosis and of pulmonary embolism. Experience of various grades of blood pressure had led him to fear the low blood pressure patient. In the prevention of pulmonary embolism the prevention and treatment of sepsis was of the first importance, and after this came measures that had for their object the prevention of stagnation in the pelvic veins.

With regard to glycosuria, the prostatic operation, like other operations, had shared in the benefit of modern progress. Glycosuria was at one time regarded as a contra-indication to prostatectomy; it was now only considered a cause for delay. Diabetes was a disease belonging to a somewhat earlier period of life than prostatic enlargement, and the point had been discussed whether senile glycosuria was the same as ordinary diabetes so far as prostatectomy was concerned. In the lecturer's view no distinction could be drawn.

While the prostate might in some cases remain in a state of moderate enlargement for a number of years—five or six—without any appreciable increase in size or amount of obstruction, the gland eventually entered on a period of more rapid enlargement. An accident such as a chill or a dietetic indiscretion would precipitate the second stage, with acute retention. But while the prostate might remain stationary for some years, it had to be remembered that the patient was growing older, and the age factor had a certain influence on the seriousness of the operation. It was the experience of urinary surgeons that the operation could be successfully performed in extreme old age. Among his own cases he had had 27 patients who were 80 years old or more, with 3 deaths. After the operation these old men might pass safely through an uncomplicated convalescence, but they had very little chance of surviving an attack of bronchitis or severe haemorrhage. In spite of the moderate death rate in prostatectomy among patients who were very old, it was impossible to be indifferent to advancing age as an argument in favour of prostatectomy being undertaken early rather than late.

THE next election to the Grocers' Company research scholarships will, as announced in our advertisement pages, take place in May. These scholarships were founded to encourage original research in sanitary science, and are each of the value of £300 a year, with an allowance to meet the cost of apparatus and other expenses in connexion with the work. They are tenable for one year, but are renewable for a second or third year. Forms of application may be obtained from the clerk to the Grocers' Company, Grocers' Hall, London, E.C.2, to whom they must be returned before the end of April.

British Medical Journal.

SATURDAY, MARCH 8TH, 1930.

A REACTIONARY DOCUMENT.

JUST over a week ago the British Medical Association and the Society of Medical Officers of Health became aware of the existence of a most important document, issued by the Ministry of Health, which affects the position and duties of large numbers of medical practitioners, and may have most serious effects on the health services of the nation. No official intimation of the issuing of this document had been given, either to the Association or to the Society, and a request by one of them for a copy was met with the reply that it was "out of print." The publication is a "Draft dated January 31st, 1930, of an Order proposed to be made by the Minister of Health under the Poor Law Act, 1927, for the consolidation, with adaptations consequent upon the passing of the Local Government Act, 1929, of Poor Law Orders." If the Rules, Orders, and Regulations contained in this draft are confirmed and issued, a blow may have been struck at Poor Law reforms, at hospital development, at health progress, and at the independence and usefulness of the medical profession from which, in many areas at any rate, recovery will be difficult. We do not place the blame for this, except technically, upon the Minister of Health, or upon the Ministry as a whole. There is yet time for them to stop the mischief if they will do so; but it is clear that the activities of the Poor Law department of the Ministry are such as to require the utmost vigilance and restraining influence. This department appears to be still living in the Elizabethan, or at least the early Victorian age, and to have an imperfect idea of the changes which the Local Government Act of last year was intended to bring about.

It will be observed that the proposed Order is "for the consolidation with adaptations" of Poor Law Orders, and the adaptations are numerous and important enough to show that they could have gone much further if there had been the will to do so. The Order is one which, if made, must not merely guide, but govern, the procedure, the methods, the machinery, the outlook of the new Poor Law authorities—that is, the councils of counties and of county boroughs. It says in so many words that it shall apply to "every Council and every Poor Law officer, assistant officer, and servant employed at the commencement of the Order or thereafter appointed by the Council." This necessarily includes all medical officers, whether part-time or whole-time, and whether employed in connexion with a hospital or institution or otherwise. Yet the Order is to consist of Rules, some of them drawn up seventy or eighty years ago, Rules with regard to the pettiest details of administration, some of which have already ceased to be accurately observed by the more progressive boards of guardians, and which are likely to prove intolerable to those who have the wider outlook and interest represented by county councils and county borough councils. In fact, this Order, if made, will present to the members of these bodies a false picture of the situation in which they begin their duties on April 1st next. It may possibly be of some value as a convenient historical review illustrating a condition of affairs, obsolete or obsolescent, which at present obtains in some parts of the country, but which Parliament and all who care for the public health had imagined would come to an end in a month's time. If the Order should be issued the memorandum accompanying it can honestly do no less than point this out, and should certainly contain the further statement that some of its Rules are set out merely for the sake of historical completeness and not as indicating what the new authorities should do.

In this draft Order there is not the least recognition that the new authorities are the administrators of other health services to which those of the Poor Law must be related. There is no hint that hospital arrangements may be varied or expanded or related to those of other institutions, after consultation with an advisory committee statutorily recognized. There is no mention at all of the medical officer of health as chief medical adviser to the council and to its Public Assistance Committee, although the Minister of Health, in an official letter to the British Medical Association,[1] has said that he "would not welcome any administrative organization which would obscure" that position. It may be argued that these vital omissions are justified by the fact that the Order is merely a consolidation of others which are unrelated to these facts. This is no justification, for that is exactly the complaint. Already the draft Order contains adjustments of one kind or another, and even refers to the creation of new officers. Further, the Rules laid down will, if obeyed, prevent or hinder the adjustments and reforms that are necessary, and will, in fact, cut across and render nugatory the arrangements which some of the larger county boroughs and a few of the counties have already made to this end in anticipation of April 1st.

No less important than these omissions is the position which the Order assigns to medical officers in relation to other officials concerned in Poor Law administration. For example: "The Council shall appoint one or more Public Assistance Officers. . . . The Public Assistance Officer shall supervise and control in the performance of their duties all officers and servants engaged on Poor Law functions." "The Master of an institution shall govern and control the institution and the officers"—including the medical officers. It may be that certain Poor Law medical officers have hitherto been working technically under Rules which, as survivals of archaic usage, have been thus archaically phrased. This is no excuse for perpetuating an obnoxious situation when, as now, the old Orders come to be rescinded and a new one made. It is intolerable that the master of a workhouse should be given the duty of governing and controlling the medical officer to the institution, or that a lay officer should supervise and control in the performance of their duties operating surgeons at a municipal hospital or any other medical officers who take part in Poor Law work.

These things together, those left out and those put in, make up, as we have said, a false picture of the duties and opportunities of the new local Poor Law authorities. Happily—also under the auspices of the Ministry of Health—we have been presented with another picture. In Chapter IV of the last annual report of the Chief Medical Officer of the Ministry there is a presentation of the situation and of the position and duties of authorities and their medical officers which is quite different from and inconsistent with the picture as set out in the draft Order under consideration. It is recognized that the two documents have a different purpose, but both pictures cannot be true. There is no doubt which

[1] *British Medical Journal Supplement*, November 22nd, 1929, p. 239.

of them was intended to be the true one, or the one to be desired by all who wish for a reformed Poor Law administration and who have regarded the Local Government Act, 1929, as a first big step towards such reform. The main business of a Minister of Health is to care for the health of the people. The Order now "proposed to be made" would be a serious hindrance to such care. It would handicap authorities in carrying on and developing their health services. It would tend to fix the less enlightened authorities in obsolete, reactionary, very imperfect methods. It would delay the proper extension of hospital provision and usage. It would prevent the cordial co-operation of the medical profession in all its branches. It would call a halt to, or even set back, that progress in national health provision upon which the community appeared to be entering with mutual good will. To try adequately to amend this draft Order would be futile. We can only urge the Minister of Health most strongly, and even at this late hour, to withdraw it.

CONGENITAL WORD-DEAFNESS.

IN the current number of the *Journal of Neurology and Psychopathology*[1] there will be found an article by Drs. C. Worster-Drought and I. M. Allen on congenital word-deafness, or, as the authors prefer to call it, congenital auditory imperfection. This condition is very rare, and so any description of it may seem to many to be of purely academic interest, but the detailed study of the reactions of the patient throw a new light on many problems of cerebral function, and illustrate the intimate connexions between physiology and psychology. For this reason the subject cannot fail to be of interest to all thoughtful physicians, for in this field we find the most paradoxical phenomena which are of the utmost importance, and at the same time not a little obscure.

The defect under discussion is analogous to congenital word-blindness, but much rarer, probably because the power of understanding written speech has been more recently acquired than the power of understanding spoken speech, and hence is more liable to derangement. The child who is afflicted with congenital word-deafness can hear but cannot clearly distinguish between sounds, or attach a significance or meaning to them. Hence he neither differentiates sounds which come to him from outside nor controls the sounds he himself emits. He is quite unable to understand spoken words unless, as we shall see directly, he has learnt to lip-read. As an infant his cry is monotonous, and does not vary with his emotional states. He is late in learning to talk, and, when he does, he easily develops a "language" of his own, which can only be understood by his immediate relations if they take great pains to learn it. He is unable to produce correct sounds of any sort, and therefore cannot sing in tune or recognize discords. The language defect is by far the most noteworthy symptom, and has been called idioglossia, having long been regarded as a disease in itself, and attributed to a special form of mental defect, the reversion to a primitive form of speech, and even to pure laziness on the part of the patient. Naturally, these children are very difficult to teach, and many of them have been regarded as idiots and segregated in institutions as such. This, however, is seldom justified, for they are found to be at least potentially normal in their general intelligence. Further, their auditory and speech apparatus are normally developed.

The condition is apt to be familial, and associated with a family history of insanity, epilepsy, and other psychopathic manifestations. There is no evidence of trauma as an etiological factor, and the distribution of the presumed lesion is difficult to assign to any lesion that could easily happen. There is no known case in which a post-mortem examination has been performed, and so any localization must be inferential; but it is presumed that the trouble is due to an aplasia of the post-temporal cortex. Sooner or later a post-mortem examination is sure to be obtained, and it will be of the greatest interest to discover whether this inference is confirmed. Among congenital defects there are not a few which are presumably due to localized aplasias causing the dropping out of specific functions without apparently interfering with general mental development. The three most obvious are: congenital word-blindness, true Little's disease, and the subject of the present study. This is certainly conclusive evidence in favour of definite localization of function in particular areas of the cortex; yet children suffering from any of these defects, if recognized early and properly taught, can learn a great deal, and even to a large extent overcome their disabilities. Their power of learning illustrates the remarkable plasticity of the cortex in taking on functions vicariously. This power has been strikingly illustrated by Lashley's experiments on the ability of rats to learn to thread mazes and perform other tricks after various areas of the cortex have been removed; but perhaps the most striking example is afforded by the work of Gault, at the Northwestern University, Chicago, who has devised a vibrator which can respond to the sound waves of the human voice. These vibrations are amplified and conveyed to the fingers of the subjects of the experiment, who are totally deaf children. Gault has succeeded in training these children to interpret these vibrations, and therefore "hear" through their fingers an ordinary lesson given by a school teacher.

In the interest of patients suffering from these conditions it is clearly desirable that all medical men should be alive to the possibilities of educating them, for it is a most obviously cruel injustice to condemn them to imbecility by deprivation of the education which is their right. In the case of the congenitally word-deaf education is admittedly difficult, for it is found that these children are often unable to understand written speech owing to a general aphasia and defect in what Head has called "internal speech," by which he means the process of translating the meaning of any given image that may be presented to the mind into a form of expression by which it can be reconveyed to the external world. They can, however, appreciate geometrical forms, and are often able to lip-read. They can copy sounds with some facility, but have great difficulty in integrating them into consecutive words. For these reasons careful individual teaching is necessary, and, owing to the tendency of the child to relapse into his idioglossia when excited or anxious to convey his meanings to others in a hurry, it may be necessary to isolate him for considerable periods while education is taking place. It has been observed that, if not taught, these congenitally word-deaf children are apt to become spiteful, asocial, and delinquent, and this is true of all those who are under-taught for any reason. The reasons for this are threefold. First, the mental activity of such children demands outlet somewhere and somehow, and if not led into desirable channels by education it will tend to follow the urges of purely

[1] *Journal of Neurology and Psychopathology*, vol. x, No. 39, January, 1930. Published by the British Medical Association. 30s. per annum, single numbers 8s. 6d.

instinctive reactions, which, being essentially individualistic, are sure to lead to asocial behaviour. Secondly, these children are apt to harbour a sense of grievance, either against fate for making them different from others, or against their elders for not giving them the same chances as others, and in their attempts to get even they may find themselves in conflict with authority. Thirdly, they may exhibit what Adler has called a psychic compensation for organ inferiority, which leads to an aggressive attitude towards the world, with considerable potentiality for evil.

It will be seen how many problems are raised by a discussion of this rare pathological condition; but this merely goes to prove that for the physician there is no limit to the field of his inquiry, and that the investigation of one problem is apt to raise a host of others all clamouring for solution.

THE L.C.C.'s OPPORTUNITY.

On April 1st the London County Council takes over the municipal hospital system of the metropolis, and as that day approaches the medical profession, particularly in London, will feel a growing desire to know what is about to happen. In the first place, it will be interested to learn whether the Council has approved any scheme for the constitution of a body which, in the words of Clause 13 of the Local Government Act, 1929, shall "represent both the governing bodies and the medical and surgical staffs of the voluntary hospitals providing services in or for the benefit of the county or county borough." As will be seen from our paragraph printed at page 463, a scheme for voluntary hospital representation in the County of London has now been accepted by the Central Public Health Committee of the L.C.C. and awaits consideration by the Council. There will be general agreement that the consultations with the new body, when it is set up, should be frequent and friendly, and that no attempt should be made to confine them within the bounds of a legal definition of the precise meaning of the clause. Whatever the wording of Clause 13 may be, the intention of the late Minister of Health—Mr. Chamberlain—was that it should be interpreted in a generous and cordial spirit, and it was his hope that the co-operation between the voluntary hospital system and the municipal hospital system should be genuine and sincere.

The L.C.C. will clearly gain much by availing itself of the accumulated experience of the voluntary hospitals, particularly in the management of the municipal hospitals which are now gathered under one control instead of being in the hands of many separate boards of guardians. The fact that all these hospitals are now grouped under single control immediately arouses an interest in them and in their development which has of necessity been lacking in the past; and the medical profession throughout the metropolitan area (forming more than a quarter of the practitioners in England and Wales) will be directly affected by the working of this vast new hospital scheme. It is, of course, clearly understood that the administration and organization of the municipal hospitals must remain in the unfettered hands of the L.C.C., and that the Council is not compelled to take the advice of the representatives of the voluntary hospitals or to act upon their suggestions. But there are few schemes, however good, that cannot be improved by wider views and fresher comments, and, however wisely the Principal Medical Officer is advised by those whom he chooses for this purpose, the burden now put upon him must be almost more than one man can carry.

The medical profession would appreciate very highly being informed from time to time not only about the organization and progress of this great hospital scheme, but also about any subsidiary schemes the L.C.C. may have in hand that bear on medical practice. Unfortunately the Council's agenda paper only becomes available to the public on the Saturday before the meeting on the following Tuesday, and there will, therefore, be little or no opportunity for the weekly professional journals to make any comment on what is coming before the Council in relation to far-reaching schemes of great importance to the medical profession.

Since the concentration of this big hospital system in the hands of the L.C.C. places a large number of medical men and women under the immediate control of one body, it is not unreasonable to hope that in any scheme of administration or organization of the municipal hospitals some place may be found for a constitutional body representing at any rate the senior medical officers in the employ of the Council, and that this body may be regularly consulted and have an opportunity of expressing its views upon any plans which involve professional aspects of the medical service and the treatment of patients. There is ample precedent for this in the almost invariable practice of the governors of voluntary hospitals to consult their medical committees before taking action in such matters. It may be objected that the L.C.C. is in a different position to the voluntary hospitals in that it has the advice of a medical officer of health of great experience. This argument, though valid to some extent, is not a complete answer, and we may repeat our point that even the ablest administrator at the head of such a vast scheme is none the worse for the considered opinion of those upon whose shoulders will be laid the burden of carrying it out.

PERIODICAL VARIATIONS IN GROWTH.

THE need for establishing normal standards of height and weight and other physical factors among children in this country has already been emphasized in these columns on more than one occasion. It is, however, a mistake to imagine that this real defect in our scientific basis of normality can be remedied by anyone possessed of the necessary measuring apparatus, and some of the difficulties connected with any investigation in this subject are well illustrated in a recent monograph by Dr. Gustav Nylin.[1] This worker was primarily concerned with the variations which occur in the rate of increase in height and weight of children, in their standard metabolism, and in the oxygen capacity of their blood. His measurements were made with the greatest care, by standardized apparatus, on large groups of school children in Spånga and Stockholm. All sorts of difficulties arose almost at once—for example, in settling the exact time of day for the measurements, for it had been observed by previous workers that boys will show a decline in height of about 1 cm. during the day, regaining this amount completely by next morning. However, Dr. Nylin was able to get round such possible sources of error, and his statistical methods appear to have been most elaborate. His results reveal a definite periodicity of growth in children during the year. The height increase showed a well-marked maximum over the period March to May, a smaller but distinct maximum during November to January, and two minimal periods—September to November and January to March. On the whole, weight

[1] Gustav Nylin. Periodical Variations in Growth, Standard Metabolism, and Oxygen Capacity of the Blood in Children. *Acta Medica Scandinavica*, Supplementum xxxi. Stockholm: D. A. Norstedt und Söner. 1929.

increase varied inversely with the height increase, a maximal period in height increase being associated with a minimal period in weight increase, and vice versa. Investigations into the standard metabolism for children about the age of 6 years showed that there was a periodicity closely connected with the periodicity in height increase, and, roughly speaking, both these factors were maximal when the radiation of the sun reached its maximum. Both in school children and pre-school children the oxygen capacity of the blood shows a periodicity, with a minimum during the dark period of the year and a maximum during the light period. These close relations between the sun's rays and increase in growth were made the object of a special experiment in which two groups of children were irradiated with ultra-violet light. It appeared from these that irradiation tends to stimulate the height increase but retard the weight increase, but the results of such experiments have to be very carefully interpreted in terms of the exact periods of the year during which they take place. Seeking for the causes of all these variations, Dr. Nylin divided possible factors into exogenous and endogenous. Among the former have to be discussed such factors as food, school, and climate. The difficulties of assessing these various possible causes are very great. The work carried out in this country on the question of milk and its influence on the growth of school children[1] is given full consideration, and many interesting observations bearing on the question of climatic conditions are put forward and discussed. Dr. Nylin is, on the whole, against the view that periodical variations in growth are due to variations in the water content of the body, and, while admitting the importance of sunlight for growth, he points out that his findings of a period of maximum increase in height during the winter months November to January are against such a connexion. On the whole, he is inclined to consider that endogenous factors are of more importance, but that these are affected by varying external factors, of which the most active is light. Precisely what these endogenous factors are is not made clear, and further inquiry is doubtless needed. Dr. Nylin's piece of work is most elaborate, and shows evidence of much laborious investigation. It should be studied by anyone who is thinking of embarking upon any anthropometric work, if only because it provides some indication of the difficulties.

COLOUR VISION.

OF recent years there has been considerable revival of interest in the question of colour vision, one of those problems of immense theoretical interest and of no small practical importance which, despite years of labour and research, seem no nearer an adequate solution to-day than half a century ago. Apart altogether from the theoretical arguments, it is known that any colour can be matched by a mixture of three primary colours; consequently any colour sensation may be regarded as the composite effect of three component sensations. The problem of the measurement of the proportions in which the three primaries participate in producing the resultant sensation must be measured on a luminosity basis, since this is the only property they have in common. From the relative luminosities of these three sensations in the production of the various spectral colours the well-known sensation curves are obtained which refer to a white light spectrum. By modifying the curves for any other distribution the trichromatic specification for any given radiation can be obtained, and by an extended application of this process any problem of colour mixing can be reduced to the fundamental terms of luminosity. All this is the result of mathematical manipulation, and does not depend on any assumption theoretically fundamental. These trichromatic colour data, with the deductive superstructure which has been erected upon them (in which the central figure is the colour triangle), have been determined several times, most notably by Maxwell (1860), König (1892), and Abney (1913); but in all of these determinations the accuracy is low and leaves much to be desired. As an addition to their already extensive series of monographs, the Committee on the Physiology of Vision of the Medical Research Council has published the results[1] of an investigation conducted by W. D. Wright of the Imperial College of Science and Technology upon this subject. There are two important points wherein new aspects are introduced into these determinations. In the first place, a new system of co-ordinates has been used whereby the units are changed from a fundamental luminosity basis to one in which the amounts of the three primary colours which make up white have equal colouring values, so that when mixed they produce a colourless sensation; that is, for white light the three primary colours are stimulated in equal proportions. In the second place, an important step forward has been taken in devising a more satisfactory trichromatic colorimeter. One of the greatest stumbling-blocks in the past investigation of this problem has been the inadequacy of the apparatus which has been devised for measuring colours. Not only has this handicap reduced the value of much experimental work, but it has entailed the somewhat unfortunate result that lack of standardization has made it difficult or impossible to correlate and compare the data of different observers. The instrument employed provides a method of filling one-half of a photometric field with a mixture of three spectral primary colours, and the other half with a spectral colour of any wave-length, and mixed, if desired, with any given amount of any spectral colour. The main experiments consisted in obtaining a series of colour matches throughout the spectrum and calculating the resultant coefficients with the new units based on monochromatic colours. The results are of importance and of considerable interest. At the same time it is freely admitted by the author that much more remains to be done. The scope of colorimetric science will always be limited until the data for what may be called a normal eye have become standardized, and there are many points in the science of colorimetry which are urgently requiring elucidation, such as the elaboration of suitable filters, determinations of sensitivity both for saturation and for hue, and observations dealing with the peripheral field and the extra-foveal retina.

MEDICAL RECORDS IN PUBLIC SCHOOLS.

THE value of the taking of records systematically and periodically in public schools was the subject of an address by Dr. G. E. Friend, medical officer at Christ's Hospital, on assuming the presidency of the Medical Officers of Schools Association at its annual general meeting on February 21st. Records of various sorts, he said, were very generally kept by and for the school medical officer, but if they were to be of definite value their method and object must be clearly thought out. Careful statistics on the clinical side were of obvious service in preventive work, and the work of the school medical officer was as much preventive as curative. One form of record would be a summarized list of all cases of illness in the school during a term, showing the duration, and the complications, if any. A card index with a card for each boy, showing after date of birth and of admission the particulars of any communicable illness from which he had suffered, was advantageous in several respects, from providing an immune team to forecasting the extent of an impending epidemic. It took only an hour of the officer's time once a term to

keep the record up to date for a school of 800 boys, and a complete list of the immune and non-immune for any disease could be made from it by a couple of intelligent convalescents in two hours. Another form of record he found useful was a spot map of the dormitories from the point of view of cases of infection. The value of dietary records was perhaps more debatable. Dr. Friend's own experience had shown that one could not safely rely on anything less than a regular analysis of the dietary, term by term when satisfactory, but week by week when things did not seem to be quite right. The dietary, of course, must be considered in relation to weight records of the boys. Dr. Friend described how he estimated the value of the proteins, fats, and carbohydrates in the cooked foodstuffs, also roughly the vitamin content. Unless one had had personal experience of such an analysis, it was impossible to realize how an apparently adequate dietary could vary, sometimes in the direction of excess of one or more constituents (generally the carbohydrate), but more often in the direction of deficiency. A third class of record, in addition to the clinical and the dietetic, was the physical. Dr. Friend said that at Christ's Hospital he was led to take up the systematic measurement of the boys towards the end of 1916, when it became evident that the war was bound to affect adversely the feeding of the school population. Amongst other measures, the weights and heights were taken at the beginning and end of each term, but before the end of the first year it was found that to watch the dietary effectively a mid-term weighing was also necessary. Measurements of the chest on full expansion and inspiration were also made once a year, at the December measuring. The object was to furnish a comprehensive check on each boy and each house, and also to show the general progress of the school by age groups in relation to diet and sickness. He had found the results so useful that he had gone on with the method although the urgent necessity perhaps no longer existed. The mere fact of seeing each boy partially stripped every six weeks was very helpful. The more experience he had of weighing as a routine the more he was convinced that it was one of the most important clinical aids the school medical officer had at his disposal. It might be objected that such work was unnecessary, that it was impossible for anyone who was not a whole-time medical officer to undertake, or that its introduction would cause irritation in various directions. He was sure that practice would show that none of these objections were valid, or if there was any substance in the third objection, it was of a purely temporary nature. The method was of real clinical value, and in view of the criticisms that appeared from time to time, chiefly in the lay press, he thought it was also useful to be in a position to bring forward evidence based on actual data that the dietaries in public schools were adequate, or, if such evidence was not forthcoming, to ascertain where they fell short of the standard necessary for growth and perfect health.

INTERNATIONAL CONGRESS OF HISTORY OF MEDICINE.

WE have just received the preliminary programme of the eighth international congress of the history of medicine, which, as we announced last week, will be held in Rome from September 22nd to the 27th. The Committee of Honour consists of His Excellency Benito Mussolini as president, Professors R. Alessandri, V. Ascoli, R. Bastianelli, and D. Giordano, and his Excellency Balbino Giuliano, the Minister of Education, as vice-presidents, and many other scientific and political notabilities. The chairman of the executive committee is Professor Pietro Capparoni, the president of the congress, with Professors Bilancioni and Castiglioni as vice-presidents. The opening meeting will be held in the Grand Hall of the Senatorial Palace and the ordinary meetings in the Accademia dei Lincei. Members of the congress will be allowed a rebate of 30 per cent. in their railway journey from the Italian frontier to Rome from September 10th to the 27th, and on their return journey from September 22nd to October 12th, as well as reduced rates in some of the principal hotels in Rome, a list of which is given in the programme. A series of attractive tours, including visits to Turin, Milan, Venice, Florence, and Padua, have been arranged before the congress by the Italian Touring Company. In addition to the usual receptions by municipal authorities and scientific bodies, the members of the congress will be received in audience by the Pope. Visits will also be paid to the galleys of Tiberius in the Lake Nemi and the monastery of Mortecassino, which formed an important place of study during the Middle Ages. Other functions are the opening of a National Museum of the History of Medicine in the recently erected Arcliio-pedale de S. Spirito in Sassi and the exhibition of manuscripts, incunabula, and rare books and prints in the Biblioteca Casanatense and Vatican library. The congress will end with a banquet, and will be followed by an excursion to the island of Cos for a "Hippocratic Day," organized by the Congress of Hydrology, which will meet in Rhodes in the second half of September. Communications are invited on any subject connected with the history of medicine, but more particularly on the first two of the following: (1) How Europe defended herself against leprosy in the Middle Ages, introduced by Professor Jeanselme of Paris. (2) The medical and scientific relations between Italy and the other European nations during the scientific renaissance in the sixteenth and seventeenth centuries, introduced by Professor Castiglioni of Padua. (3) On the need for making the study of the history of medicine a compulsory subject in all universities, introduced by Professor Ladislao Szumowski of Cracow. The subjects of papers should be communicated to the secretary by April 30th, and after the papers have been read a typewritten copy, which should not exceed ten large octavo pages, should be sent to the secretary for insertion in the *Proceedings*. The subscriptions are as follows: for members of the International Society of the History of Medicine and members of the Italian Society of the History of Medical and National Sciences 100 lire; for all other members of the congress 150 lire; for members of the family of those taking part in the congress and medical students 50 lire. Those wishing to take part in the congress should signify their intention without delay to the general secretary, Dr. Filippo Rocchi, Corso Vittorio Emanuele 173, Rome.

A LONDON MEDICAL GUIDE.

IN *The Medical Signpost*[1] Dr. T. T. B. Watson and Dr. Alfred Welply have given the London practitioner a guide for which he should be grateful. In a modest prefatory note they claim that the handbook gives easy access to information "which a practitioner daily requires, and which he is often unable to obtain without considerable inconvenience and delay." A glance at the contents suggests that the claim is justified. The book is divided into three parts, of which the first gives general information as to the source, the method of obtaining, and in many cases the cost of the various services which the practitioner may from time to time require in his own work, or wish to obtain or advise for his patients, of whatever class, and also as to his obligations under a number of Acts and Regulations. The second indicates the various services, municipal and voluntary, available within each of the metropolitan boroughs; and the third is intended for notes on the conduct of the individual practice, to be made by the principal for the benefit of any locumtenent in whose charge it may be left,

[1] *The Medical Signpost*, 1930. Compiled by T. T. B. Watson, M.B., B.Ch., and Alfred Welply, M.D. Enfield, Middlesex: Stanley Woodfield. 1930. (Demy 8vo. Pp. 215. 10s. net.)

with a spare page for a sketch map of the district. The arrangement throughout the book is alphabetical, even to the third section, where printed headings are inserted to ensure against omission of any of the main points essential to the efficient working of a practice in the absence of the principal. It is therefore seldom necessary to consult the index or table of contents. The cross-references required by the alphabetical arrangement seem adequate without being cumbersome. In producing a book of this type the necessity for boiling down a great mass of information almost to dryness makes it difficult to avoid false emphasis, if not real inaccuracy. This danger the compilers have tried to meet by confining themselves to the points most likely to cause practical difficulty, and referring the reader, under each head, to an authoritative source of detailed information where such exists. It is not surprising, however, if some points remain where modification appears desirable. For example, on page 19, under "Dangerous Drugs Acts," there is a statement that the "penalty for not keeping records correctly through inadvertence is a fine not exceeding £50." This surely needs elaboration if it is not to convey a false idea of the general tenor of the Acts. Inaccurate record keeping through inadvertence is not a distinct offence. The fact is that prosecution can only be instituted with the consent of the Attorney-General or by the Director of Public Prosecutions, so that it is unlikely to be based solely on minor inaccuracies. The limit of £50 is only applicable to a case in which the court is satisfied that the error was in fact due to inadvertence, and in no way connected with the commission or intended commission of any other offence against the Act. On page 36, if the income limit under the National Health Insurance Acts is mentioned, it should be explained that this is not applicable to manual workers. The address of the National Ophthalmic Treatment Board is not, as stated on page 43, B.M.A. House, but 1, High Street, Marylebone, W.1, though information about local ophthalmic services may be obtained from the Medical Secretary, B.M.A. House, as well as from the Board. These and other minor defects will doubtless be rectified in future editions of a very useful work.

PSITTACOSIS IN THE ARGENTINE REPUBLIC.

IN a communication to the Seventh Congress of the Argentine Medical Association on November 29th, 1929, Dr. Enrique Barros,[1] professor of morbid anatomy in the University of Córdoba, gives a full and interesting account of the severe epidemic of psittacosis which broke out suddenly in Córdoba last July and August on the occasion of an exhibition of birds in that city. The disease was at first mistaken for enteric fever or malignant influenza, but presented several atypical features which did not correspond to either of these diseases. Its true nature was discovered by Professor Barros, who eight years previously had made a study of the literature of psittacosis in Aschoff's Institute of *Morbid Anatomy* at Freiburg. Inquiry showed that all the cases had occurred among individuals or families who had purchased parrots at the exhibition. Subsequently cases occurred in Alta Gracia and Tucuman, which were traced to parrots purchased at Córdoba. Isolated outbreaks at Buenos Aires, which bore no relation to the Córdoba epidemic, also developed, resembling the similar small outbreaks in France which followed the great epidemic of Paris in 1891–92. Professor Barros contributes brief histories of 64 cases which occurred at Córdoba, and a discussion of the clinical and bacteriological aspects of the disease.

THE KING has appointed Dr. Maurice A. Cassidy, C.B., F.R.C.P., physician to St. Thomas's Hospital, to be physician to His Majesty's Household in succession to Dr. Herbert French.

PEPTIC ULCER.

A REVIEW OF THE COLLECTIVE INQUIRY.

BY

LORD MOYNIHAN OF LEEDS,

PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

DR. ARTHUR P. LUFF has now concluded his report on the "Collective Investigation" of cases of peptic ulcer.[1] The labour has been arduous and responsible; and has contributed something of real value to our knowledge, something of a kind which has, I think, no parallel in other countries. The raw material for the inquiry came from a number of sources; no individual surgeon appears to have contributed a large proportion of the total, and the results, in consequence, are to be regarded as indicating the average which may be attained by competent workers throughout the country, rather than the highest results within the experience of the most skilful.

In a letter to the *British Medical Journal* (January 4th, p. 40) I criticized the word "pyloric" as used to indicate the position of a group of ulcers. There is no doubt that this word is very loosely and very inaccurately used, and that we should more clearly understand what we are talking about if the word disappeared altogether from surgical literature. It is only a peg upon which to hang the half-truths. If cases of "pyloric" ulcer are all included among cases of duodenal ulcer probably the truth of the matter would suffer little damage.

The results of the investigation in many instances corroborate and fortify the general impressions derived from the experience of the last quarter-century; in other cases they act as a useful corrective.

Duodenal ulcer, including pyloric ulcer, was found to be far more common in males than in females; and rarely originated after the age of 50. It was frequently associated with, and appeared therefore to be in some degree dependent upon, or perpetuated by, hyperchlorhydria. As the appropriate method of surgical treatment the operation of gastro-enterostomy was chosen in approximately 95 per cent. of cases. The average mortality was in the neighbourhood of 4.5 per cent., the "good" results about 90 per cent. Gastro-jejunal ulcer occurred more often than the figures appear to indicate; for I think it is certain that in many cases, if not in all, in which severe pain (6 per cent.) or haemorrhage (2.4 per cent.) was present after the short-circuiting operation, an ulcer was the cause; the ulcer may have been the old ulcer, a new one near to it, or at the anastomosis. If this is so the incidence of gastro-jejunal ulcer would appear to have been almost 10 per cent.; a figure which Hurst and Stewart would probably regard as too low, which I regard as far too high. Some of the causes of death were preventable. Nowadays we should hear nothing of "shock" as a cause of mortality in such operations as gastro-enterostomy. When surgeons consistently spend as much care over the preliminaries of operation as over the operation itself; when, that is to say, a patient is adequately prepared for operation by such measures as transfusion of blood, administration of glucose, dental toilet, and so forth, "shock" will surely not occur. The mere craft of surgery has, I think, almost reached its limits, few operations can be conceived that have not already been practised, few organs remain aloof from surgical interest, no great improvement will occur either in technical methods or in immediate and remote results. If ulcer of the duodenum, and ulcer or cancer of the stomach, for example, are to be treated by operation, it is not possible to obtain much better results than are within our reach to-day. We may learn to avoid operation by checking the development of these diseases, or we may

[1] *British Medical Journal*, December 7th and 14th, 1929, and February 22nd, 1930.

find other ways of treating them when developed, but the craft of surgery in itself can do little more for us. In the most practised hands the mortality of operations in cases of duodenal ulcer, for example, is well below 1 per cent., and there is not much room for improvement there. What can be done, however, is to bring average results up to the best by adopting the methods of the most successful surgeons, and these are concerned not so much with dexterity, rapidity, or any magical manipulative skill, as with simple unremitting care, before, during, and after operation.

Medical treatment subsequent to operation was necessary in 4.5 per cent. of cases. It should be a matter of routine in all cases. In my own practice I give to every patient after operation two printed papers, one indicating the ordinary daily diet, the other the foods or the conditions to be avoided; charts of abstinence and of indulgence. Such precautions are really necessary, for otherwise patients, feeling better than they have done perhaps for years, are a little prone to be reckless, and tobacco is hardly recognized as an enemy.

The final report of cases of *gastric ulcer* shows that our general opinions, based upon post-mortem knowledge and the experience of the operation room, are well founded. Ulcers of the stomach were found oftenest upon the lesser curvature; ulcers near the pylorus were comparatively rare. Hyperchlorhydria was found in 40 per cent. of cases; and a low acidity in over 50 per cent. The old view promulgated in days not long past when gastric ulcer was confused with duodenal ulcer, that hyperchlorhydria was an almost invariable, and probably causative, condition in cases of gastric ulcer is shown once again to be unfounded.

The operations preferred by the contributors to this series of reports are not always those upon which many surgeons are now accustomed to rely.

Posterior gastro-enterostomy alone was performed in nearly 50 per cent. of cases, and gave only 50 per cent. of good results. I am a little surprised that the results were even so satisfactory. It is approximately twenty years since I abandoned the operation of gastro-enterostomy for gastric ulcers, unless distal to the position of the suggested new opening, or there were grave reasons forbidding gastrectomy; such reasons, as a matter of experience, are infrequent. My friend Mr. Herbert J. Paterson has never quite agreed with me upon this matter. He still contents himself with the short-circuiting operation. I have found the operation of gastrectomy for gastric ulcer to be far more satisfactory, and very safe; I have yet to meet a case in which the ultimate result was disappointing; and secondary operations are almost unknown. The operation of gastrectomy has the advantage of difficulties. The grave disadvantages of gastro-enterostomy are not only its ineffectiveness in encouraging an ulcer to heal, as these statistics show once again, but also centre round the case of its performance; for a multitude of operations have been needlessly and crudely performed for a variety of diseases for which a short-circuiting operation is utterly unsuited. The consequence is that physicians and others who see these cases only, and fail to take into account the condition for which the operation was improperly undertaken, are apt, very wrongly of course, though perhaps naturally, to condemn the operation, merely as an operation. The condemnation should reach, not the operation, but the operator, for experience shows, beyond cavil, that, judiciously applied and skilfully performed, there is perhaps no major operation whose admirable results, early and late, surpass those of gastro-enterostomy. Gastro-enterostomy alone as applied to gastric ulcer is, however, not satisfactory; the ulcer itself must always be treated, wherever it lies. It is made clear by this investigation that the immediate results of gastro-enterostomy, for both gastric and duodenal ulcers, are better if the ulcer is directly treated. The following tables show this:

	Duodenal Ulcers.	Pyloric Ulcers (mostly Duodenal).	Gastric Ulcers.
Posterior gastro-enterostomy with removal or infolding of ulcer. Post-operative mortality (percentage).	1.8	1.3	4.6
Posterior gastro-enterostomy without interference with ulcer. Post-operative mortality (percentage).	5.7	2.5	11.4

The advantages of the operation when combined with removal or infolding of the ulcer are also remarkably demonstrated by the number of "very good" results obtained. These results show the number of patients restored to full health, able to take any kind of food over periods of some years, and able to resume full work.

	Duodenal Ulcers.	Pyloric Ulcers (mostly Duodenal).	Gastric Ulcers.
Posterior gastro-enterostomy with removal or infolding of ulcer. Percentage of very good results.	81.2	72.4	91.7
Posterior gastro-enterostomy without interference with ulcer. Percentage of very good results.	64.5	44.7	50.9

Nevertheless too much reliance must not be placed upon these figures; for a difference in the skill and competence of the surgeons concerned in the treatment of each group may be enough to account for differences in the figures. There are, so far as my direct observation goes, few surgeons of wide experience who do not deal directly with an ulcer wherever it may lie, and these are the very men who might be expected to ensure the best results.

The operation of gastro-enterostomy alone should therefore in my judgement no longer be considered adequate in any form of peptic ulcer. In cases of ulcer of the stomach it may be combined with the cauterization of the ulcer (Balfour's method) or with excision of the ulcer. Mr. A. J. Walton, a most expert and accomplished surgeon, prefers the latter method, which in his nimble hands shows a low mortality and a high proportion of good results. The operation has the advantage of conserving a large part of the stomach, and in this series gave over 80 per cent. of "very good" results with a post-operative mortality of 4.6 per cent. It is interesting to observe that partial gastrectomy, performed in 101 cases, had a mortality of 6 per cent., and the "very good" results are only 63.6 per cent. This is quite contrary to my own experience, which in numbers greatly exceeds the total here investigated. I am whole-heartedly in favour of gastrectomy when the operator can confidently expect a mortality hardly greater than that of gastro-enterostomy.

Gastro-jejunal ulceration occurred in three cases in which it was recognized and treated by further operation, and probably in other cases when severe pain and haemorrhage were present. The general mortality for all types of operation was almost 9 per cent., which is higher than it should be. No case of ulcer leading to cancer was observed in this series. Medical treatment was found to be necessary after operation in "several" cases.

The report concludes with the cases of hour-glass stomach. It is interesting to me to observe that 65 cases are analysed: for when long ago I wrote the first surgical paper on this subject I could find in all the literature, and upon museum shelves, evidence of only 40 cases

recognized by previous observers. Gastric ulcer was found to be twice as frequent in males as in females; yet hour-glass stomach was five times as frequent in females. Partial gastrectomy was the operation selected in one-half the cases. An operation which in the absence of pyloric stenosis has served me extremely well, gastro-enterostomy, was not performed. The general mortality, 12.3 per cent., is high. Good results followed operation in 90 per cent. of the survivors. No case of ulcus carcinomatosum was observed.

Dr. Luff has taken great pains to tabulate all the information placed at his disposal, and the solid success of his labours is evident to all. In surgery, however, there are influences beyond the reach of tabulation, and individual rather than collective opinions will surely continue to control our thoughts and actions.

May I express the thanks and convey the congratulations of all members of our Association to Dr. Luff, and suggest to him that a similar investigation as to the results of medical treatment for these conditions might well prove informative.

MATERNAL AND CHILD WELFARE IN AUSTRALIA.

DAME JANET CAMPBELL'S REPORT.

THE trend of the statistics relating to maternal mortality in Australia, as shown in Dame Janet Campbell's report,[1] to which we made brief reference in our issue of February 22nd (p. 346), is in striking contrast with that of the statistics relating to the mortality of infants under 1 year—a state of affairs which is paralleled very closely in our own country. Almost stationary between 1911 and 1922, since 1922 the maternal mortality has risen steadily and almost without interruption in every State in the Commonwealth, the rate in 1928 reaching the disquieting figure of 5.98 per 1,000; yet, during the same period the death rate of children under 1 year per 1,000 live births has fallen almost steadily, reaching in 1928 the lowest level yet recorded—namely, 52.96. It may be suggested that the tendency of the maternal death rate to rise is only apparent, and attributable to the increasing accuracy in recording the exact causes of death; or that the explanation lies in the rising proportion of first births associated with a declining birth rate. From the immediate and practical point of view such possible inaccuracies may be disregarded, and the fact must be faced that in Australia, as here, there is an increasing maternal death rate, in spite of improving standards of hygiene and the advance of modern medicine.

Maternal Mortality.

In analysing the causes of maternal mortality during 1919-28, Dame Janet Campbell found that an unduly large proportion of deaths might have been avoided if circumstances had been more favourable; thus, whereas in England and Wales during this period only one-tenth of maternal deaths were due to accidents of pregnancy, including abortion, in Australia deaths from this cause numbered about one-seventh of the total. The incidence of fatal abortion appears to be higher in Australia than it is here, though how far this state of affairs is due to natural causes and how far to criminal interference is a question that cannot be answered in the light of available data. Of the other causes of maternal mortality, puerperal sepsis—the most important—accounted for nearly one-third of the deaths at the time of childbirth. Toxaemia accounted for rather more than one-fifth, haemorrhage for about one-eighth, and accidents of childbirth, chiefly due to difficult labour, for about one-tenth. These figures are far from representing the total toll of childbirth; for every woman who dies as the result of child-bearing many others are injured more or less seriously, and there is no way of measuring accurately the extent, or the social or domestic effects, of maternal morbidity. Furthermore, a high maternal mortality and morbidity involves the loss of many infant lives from causes which kill or maim the mother, the maternal mortality rate indeed being so intimately associated with the neo-natal death rate that measures which are successful in reducing the former will, Dame Janet Campbell believes, assuredly also lead to a reduction of the later.

Infant Mortality.

The tables representing the infant mortality during the period 1901-28 reveal a very different picture. At the beginning of the century the infant death rate in Australia was 96 per 1,000 live births; in 1928 it was 52. The decline affects chiefly infants in the 1–12 months period, whose mortality rate has been reduced from an average of 63 in the first five years of the century to 24 in 1928. In the same period the death rate of infants under 1 month has fallen very little, and the death rate of infants in the first few days of life has even shown a slight tendency to rise. Some such figures are what one might have expected. Deaths during the first week are due to obstetric and developmental rather than to pediatric causes, and measures which are successful in reducing mortality after the first month have but little effect in protecting the younger babies. A relatively high maternal death rate is always likely to be associated with a correspondingly high neo-natal death rate.

There is no registration of stillbirths in the Commonwealth, but from information obtained through the maternity allowance returns it appears that the stillbirth rate averages about 30 per 1,000 live births and remains fairly constant. This rate corresponds closely with that shown in the English returns, which, until 1927, when the registration of stillbirths came into force, averaged fairly constantly 30 to 33 per 1,000 live births. Some of these deaths are, of course, unavoidable—those, for example, due to congenital defects—but a reduction of stillbirths and of neo-natal deaths might be expected to result from improved maternal hygiene and more efficient care of the premature, delicate, or debilitated baby during the early weeks of life.

Facilities for Infant and Child Welfare.

The practical problems of maternal and child welfare in Australia are complicated by the fact that throughout the Commonwealth there are great, sparsely inhabited districts, where communities may be widely separated from one another and the standard of convenience is very different from that in the towns. To some extent these problems are being met by various voluntary agencies, and for most of their activities official support is now available. In every State there are a number of infant welfare centres staffed by qualified nurses, who also visit in the homes. These centres resemble private clinics, and are very different from some of the busy municipal centres in this country. They are attended by women of all social classes, there being no sharp dividing line of poverty to separate Australian mothers into different groups. On the other hand, medical control is more or less perfunctory, largely, suggests Dame Janet Campbell, because most of the mothers have their own family doctor, to whom the baby is taken in case of illness, in part to emphasize the fact that the centres have a strictly limited function and are not concerned with the cure of disease.

As in England, there is an unfortunate gap between the time when the infant ceases to attend the centre and its admission to school, when it comes within the care of the school medical service. In an endeavour to bridge this gap various voluntary agencies, operating in the larger cities, have established day nurseries and free kindergartens; but though most of these receive Government recognition and financial aid, they are quite inadequate to cope with the problem as a whole.

Maternal Welfare.

Practically all maternity hospitals in large centres have ante-natal clinics attached to them, but on the whole facilities for systematic supervision of pregnancy are inadequate: thus, ante-natal work has scarcely developed at all in connexion with infant welfare centres, and only here and there has an ante-natal clinic been started

[1] Report on Maternal and Child Welfare in Australia. By Dame Janet M. Campbell, D.B.E., M.D., M.S., Senior Medical Officer for Maternity and Child Welfare, Ministry of Health, London. H. J. Green, Government Printer, Canberra, Australia.

experimentally to see whether it will prove popular with the women. The provision of maternity beds seems good; many maternity hospitals in the larger centres have made, or are undergoing, alteration, with a view to meeting modern requirements more adequately; new maternity wards have been added to the general hospitals in country districts, bush nursing hospitals are being provided in districts too sparsely populated to support larger institutions, and it seems as if the supply of accessible maternity beds will keep pace with the demand for in-patient accommodation.

Bush nursing associations exist in all States, except South Australia, for the purpose of providing medical, nursing, and domestic help for women in isolated districts. The nurses are fully trained, and possess a midwifery certificate, in addition to which they are now encouraged to obtain a certificate in mothercraft. Dame Janet Campbell makes special mention of the admirable work of the Australian Inland Mission, under the auspices of the Presbyterian Church, which has organized nursing and medical aid in some almost inaccessible districts, and has now twelve well-equipped stations in the interior.

Suggestions for Future Action.

From her review of the present position in Australia the author concludes that the time has arrived when effective development depends on securing an agreed policy, in order that the work as a whole may be rendered efficient, scientific, and not unduly dependent on the good will and generosity of individuals; above all, that it should take its proper place in organic relation with other branches of public health work. At the forefront of her proposals she puts improved professional education in midwifery and infant hygiene, pointing to the action of the Universities of Sydney and Melbourne in creating professorships in obstetrics as an indication of the increased importance now being attached to midwifery and as a first step towards much-needed reforms in the curriculum. The real difficulty is the provision of adequate facilities for clinical study, and Dame Janet Campbell suggests that if, in any training institution attached to a medical school, there is not sufficient opportunity for the proper teaching of both medical students and midwives, the students should always have preference, and midwifery pupils should not be accepted until the requirements of the students can be adequately satisfied. Provision of post-graduate instruction is recommended as a means of encouraging older and more isolated practitioners to realize the advantage of systematic ante-natal supervision and of co-operating with any scheme for maternal and infant welfare which may be in operation in their districts. While it is desirable in the training of midwives to use maternity institutions as extensively as possible, it is recognized to be of greater advantage to train a small number of midwives efficiently than to allow certification after instruction which falls below the minimum requirements. Training in mothercraft, now looked upon in Australia as an essential qualification for all infant welfare nurses, should, in Dame Janet Campbell's view, receive full official recognition and support. To secure a uniformly high tradition and standard of instruction it would be as well to lay down general regulations to which all approved mothercraft schools should be expected to conform; for example, that the whole of the course should be under medical direction and control, and that the accommodation, facilities for teaching, qualifications and equipment of the staff, length of the training period, and so forth, must reach a certain minimum standard.

A further group of recommendations is concerned with modifications in legislation and administrative machinery, whereby the data essential to a correct understanding of the problem under review might be more accurately collected, and the work of child welfare organizations and maternal welfare schemes facilitated and improved. These recommendations cover the institution of a uniform system for recording maternal deaths, registration of stillbirths, and notification of births throughout the Commonwealth, and the revision of the arrangements for the notification, prevention, and control of puerperal sepsis. A certain amount of puerperal sepsis occurs in connexion with septic abortion, much of which is said to be self-induced; this is a matter which would repay investigation, not only in order to ascertain the extent of the mischief, but, if possible, to control it.

Having outlined the main requirements of an effective maternity service, taking in pre-natal supervision, the confinement, domiciliary and institutional midwifery, post-natal care and auxiliary assistance, and considered the problems facing the infant and child welfare services, Dame Janet Campbell proposes that, to meet the special conditions obtaining in the Commonwealth, a properly organized division of maternal, infant, and child welfare should be established in each State as a branch of the health department, under the control of a whole-time medical director, responsible to the chief medical officer of health. This division should be made responsible for the supervision of all matters concerned with the welfare of expectant and nursing mothers, and of children under school age as far as these can properly come within the scope of the State health department as part of the public health service. It is evident, from an examination of the activities now in being, that, whereas much valuable work has been accomplished in health education since the initiation of the welfare movement by voluntary agencies, a point has been reached at which the detachment of these activities from the practising medical profession, and from the official health agencies, is a serious handicap to further development and satisfactory results. The enlistment of voluntary agencies under the staff direction of the State health department has become essential to successful development of the maternal and child welfare service.

It is fully recognized that the organization suggested for each State is beyond the present resources of some States, and it was no doubt to meet difficulties of this kind that the Royal Commission on Health recommended that the Commonwealth Government should assume some degree of active responsibility; this the Government has already done in passing the Maternal Allowance Act of 1912, and no departure from established policy would seem to be involved in a more definite participation in the work of safeguarding maternal and infant health. A national centre is essential for, among other activities, the collection of information, the examination of problems on a national scale, the investigation of work done by the State authorities, and the encouragement of research. Dame Janet Campbell suggests that the establishment of a division of maternal and child welfare as part of the Commonwealth Department of Health would be a step which the Government could most profitably take, and records as her considered opinion that a medical woman should be appointed director of the division, if one can be found with the necessary personality and qualifications. Further action of the Commonwealth Government, she proposes, should be in the direction of granting subsidies, properly conditioned and adequately supervised, towards the extension and improvement of the work for maternal, infant, and child hygiene, and the encouragement and subsidizing of research into various aspects of such activities.

Scotland.

Elsie Inglis Memorial Hospital.

THE completed Elsie Inglis Memorial Maternity Hospital and Nurses' Home, Edinburgh, was formally opened on February 28th by Mr. William Adamson, Secretary of State for Scotland. Lord Provost Whitson, who presided, congratulated the executive committee of the hospital on the successful completion of its work. Mr. Adamson said that the Queen desired him to convey an assurance of her keen interest in the welfare of that hospital. Its work had been developed by women, and its staff consisted entirely of women. The hospital was accessible, and had a splendid outlook on the King's Park on the south. In referring to maternal mortality, Mr. Adamson said that the sixty beds provided by the hospital and its fifteen ante-natal beds formed an important contribution to the solution of this problem, which was a very urgent one in Edinburgh. Many more beds, however, were urgently required, and he hoped that the corporation of Edinburgh and the parish council would find adequate accommodation until more permanent provision could be made. The present hospital,

he added, was a worthy memorial to the woman who was the first to provide maternity care for working-class women in Edinburgh in the hospice in the High Street. Miss Chadburn, M.D., of London, said that she represented the London hospitals, where about 400 beds, distributed among five hospitals, were under the charge of women. These 400 beds required a working income of £60,000 per annum. After the opening ceremony a dinner was held in the Caledonian Hotel, Edinburgh, at which Mrs. Whitson, the Lady Provost, presided. "The Success of the Elsie Inglis Maternity Memorial Hospital" was proposed by Dr. Jane Walker. In proposing the toast of "Sister Hospitals," Dr. Joan Rose referred to the Elsie Inglis Memorial Hospital at Belgrade, where she said those who had served with the Scottish Women's Hospitals in the war were still remembered.

Milk and Nutrition.

At a meeting of the Scottish National Milk and Health Association, held in Glasgow on February 21st, Mr. W. J. Harvey, treasurer of Edinburgh, who presided, referred to the large-scale experiment which had just been inaugurated in Lanarkshire in feeding school children with milk (*British Medical Journal*, February 22nd, p. 357). The experiment, he said, was the result of two similar experiments that were undertaken several years ago by that association. There was still much prejudice against milk, particularly as a food for adults. The association had the support of the medical profession and the local authorities, and the milk industry should utilize this opportunity for more intensive propaganda. Dr. Gerald Leighton of the Department of Health for Scotland said that investigations had originally been carried out with 1,000 children, but this number was not regarded by statisticians as sufficient to warrant generalizations of any significance. He hoped that, as the result of the present experiment with 20,000 children, they would be able by this time next year to advocate a policy of giving children as much milk as they could digest. Mr. A. W. Hunter, referring to the testing of cows, said that the farmers complained that the authorities would not lay down a definite test; tests differed in various counties. Responsibility for clean milk rested primarily with the farmer, but he thought that local authorities themselves should observe the regulations more strictly.

In the annual report of the education authority of Glasgow, submitted at the statutory meeting on February 20th, reference was made to an investigation upon the nutritive value of milk which had been carried out in Glasgow. During the first year of the experiment children receiving milk had shown an increase of 21 per cent. in height and weight over those receiving biscuit, while in the second year the increase in height had been 23 per cent. and in weight 45 per cent. This investigation had emphasized the value of separated milk, which, being cheap, could be added with advantage to the diet of growing children where fats, such as butter or margarine, were otherwise sufficient.

Edinburgh Hospital for Crippled Children.

The Hospital for Crippled Children at Fairmilehead, Edinburgh, whose foundation stone was laid by H.R.H. the Duchess of York last October, is advertising for a surgeon. It has been arranged between the committee of the hospital and the University of Edinburgh that a university lectureship in orthopaedics will be associated with this appointment. A small committee, consisting of three members appointed by the hospital and two by the university, will nominate a candidate for the joint position. The salary will be £1,000 per annum, and the surgeon appointed will probably be required to confine his private practice to orthopaedic surgery. It is not expected that the hospital will be opened until 1932, but the appointment is being made now so that the advice of the successful candidate may be available in regard to details of construction and the arrangement of the work affecting the major and minor clinics which are to be established in the South-East of Scotland. A sum of nearly £60,000 has been subscribed towards the £75,000 required to complete the hospital, which will deal with orthopaedic work not only in Edinburgh but in the counties of the Lothians, Peebles, Selkirk, Roxburgh, Berwick, and the western half of Fifeshire. About seventy-five beds will be provided at first. Particulars of the appointment may be obtained from the honorary secretary, Edinburgh Hospital for Crippled Children, 5, Hill Street, Edinburgh.

Relief of Incurables in Glasgow.

At the annual meeting of the Association for the Relief of Incurables in Glasgow and the West of Scotland, on February 26th, Lord Provost Kelly, who presided, said that 354 patients had been cared for by the association last year. Of these, 145 were in Broomhill Home, 75 at Lanfine Hospital for Consumptives, and 144 had been treated as outdoor patients. In Broomhill Home, at the end of 1929, there were 23 patients with an average residence of over twenty-two years, and 23 with an average of fourteen and a half years. An appeal was now being made for contributions to extend this home. These institutions, in being both homes and hospitals, were unlike any other charitable institutions in the district. Referring to their financial position, the Lord Provost said that the contributions of the employees during the past year had never been exceeded. The contribution of the Ladies' Auxiliary, amounting to £2,379, was also a record.

Red Cross Work in Edinburgh.

The annual meeting of the Edinburgh Red Cross Committee, held in the City Chambers, Edinburgh, on February 25th, was presided over by Lord Provost Whitson. The report showed a satisfactory financial position. During 1929 many books, magazines, and gramophone records were received and distributed to military and civilian hospitals in Edinburgh and Midlothian. The emergency help scheme, inaugurated in 1921 to assist ex-service men, had been maintained; and assistance was given in 28 cases at an expenditure of £116. The strength of the Edinburgh Voluntary Aid Detachments was 125 mobile members and 135 immobile members, an increase of 18 in the number of mobile members. At a hospital organized for the 156th Infantry Brigade at Riccarton for a fortnight in July, 1929, 20 in-patients and 476 out-patients had been treated. Arrangements have been made for a V.A.D. camp to be held this summer at Gosford House, Aberlady. In referring to the high efficiency of the Edinburgh Voluntary Aid Detachments, Colonel Wood, D.D.M.S., Scottish Command, remarked that the percentage of mobile members in Edinburgh was the highest in Great Britain.

Neurology and Surgery.

Sir Charles Ballance delivered a lecture in Glasgow University (under the Macewen Memorial Foundation) on February 28th, on "The dawn and epic of neurology and surgery." Principal Rait presided. In paying tribute to Sir William Macewen's exceptional judgement, the lecturer said that the pathological investigation pursued during the first seventy years of last century had laid the foundation of the more perfect clinical diagnosis of the present day, and rendered advances in surgery possible. A neurological surgeon must be a trained physiologist before he began to operate on the nervous system. Surgery and medicine owed as much to-day to the experimental method as to the discoveries of anaesthesia and of the microbic origin of disease. It was difficult for those who had recently joined the profession to realize how surgery was paralysed sixty years ago by the presence of sepsis, tetanus, hospital gangrene, and other wound diseases, for which no means of prevention had been discovered. The lecturer remarked that the most glorious period in the history of surgery had occurred during his own lifetime. The art and science of surgery was still progressing.

Post Office Medical Officership.

At a social gathering in the General Post Office, Edinburgh, Dr. K. M. Douglas, who had been medical officer to the Post Office there for forty-two years, was presented with a wireless set. Mr. James Munnoch, controller, who presided, said that Dr. Douglas had succeeded his father as medical officer, so that the combined service of father and son extended over seventy years. On Dr. Douglas's retirement a short time ago, four medical officers were appointed for the postal service in different parts of the city.

England and Wales.

Voluntary Hospital Representation for London.

THE scheme for voluntary hospital representation in the County of London for the purposes of Section 13 of the Local Government Act has been accepted by the Central Public Health Committee of the London County Council. This scheme, which is put forward by the King Edward's Hospital Fund for London, the Conference of Teaching Hospitals, and the London Regional Committee of the British Hospitals Association, rests on the basis that each hospital shall nominate its own representatives on electoral bodies and committees, by whom a central committee of forty shall be elected. The Central Public Health Committee states that certain points which it had raised have been satisfactorily met in the scheme. One of these points was that, for the purpose of consultations between representatives of the Council and of the voluntary hospitals, the committee of forty should nominate not more than five or six representatives to express their views, and this has been promised. The Central Public Health Committee is satisfied that the new scheme secures adequately the representation of voluntary hospitals contemplated by Section 13.

Central Association for Mental Welfare.

The fifteenth report of the Central Association for Mental Welfare (24, Buckingham Palace Road, S.W.1) places in the forefront a note of gratitude to its president and chairman of executive, Sir Leslie Scott, for his real and practical help in carrying through negotiations with the late Minister of Health, ensuring the position of mental welfare work under the Local Government Act. The hope is expressed that that great measure will have a most far-reaching influence in securing the continuity of care and control over defectives which has long been earnestly desired by all concerned with their welfare. The unification of public health services under one authority, the definite recognition that public health includes mental as well as physical health, and the further recognition of the important part played by voluntary societies in the sphere of public health, are all felt to be factors which should lead to a great expansion in mental welfare work in the near future. The report contains particulars of the development of the work in new areas; local mental welfare associations have been started during the year under review in Sunderland, Darlington, Leicestershire, Oxfordshire, and Bournemouth. The report also describes the considerable educational work which is being carried out, including the organization of training courses in mental welfare work for teachers, medical officers, and others. Occupation and handicraft centres are rapidly increasing as a result of the Mental Deficiency Act, 1927, by which local authorities are bound to provide training for defectives under supervision. The reports of the local associations which are appended to the report of the central body show what great extension is proceeding in this respect. The important work of the case department is one which cannot be tabulated in figures, although an attempt is made to do so. The main work consists in advising local authorities, parents, and friends of facilities for treatment and training, and as to procedure. The Middlesex County Council has agreed to pay a block grant of £2,094 per annum to the association for the organization of occupation centres and home teaching in the county.

District Nursing in London.

An important period of adjustment is foreshadowed in the fifteenth annual report of the Central Council for District Nursing in London, in consequence of the operation, in April next, of the Local Government Act of 1929. This Act will have far-reaching effects on district nursing, by transferring the duties of the boards of guardians to the London County Council. In the London area extensive changes have occurred during the year. Owing to serious financial difficulties, the work of the St. Pancras District Nursing Association has been taken over by the Metropolitan Association, which has established a branch home with five resident nurses in the district. Nursing arrangements have also been systematized in several other districts, and new associations employing Queen's nurses have been started in Middlesex for Stanwell and Northolt, both on a provident basis. The total awards made to district nursing associations in 1929 amounted to £4,412, which included £750 from the reserve funds of the council. In addition to the £3,000 entrusted to the council by the trustees of the London Parochial Charities, £400 was also given by the trustees for the administrative work of the council, and £200 was granted for bursaries. Contributions were also received from the Society of Apothecaries, the Companies of Armourers and Braziers, and Ironmongers, and from the Grimthorpe, Samuel Lewis, Peabody, and Guinness trustees. A new *Supplement* of the *Directory of District Nursing* has been published, incorporating the issue of 1927 and the subsequent changes that have taken place.

University of London Medical Graduates Society.

The first meeting and dinner of medical graduates of the University of London resident in Manchester and district was held on February 28th, at the Midland Hotel, Manchester. Sir StClair Thomson, president of the University of London Medical Graduates Society, was in the chair, and among those present were Mr. W. McAdam Eccles (honorary treasurer), Dr. Dorothy C. Hare (joint honorary secretary), Dr. R. H. B. Adamson, Mr. William Billington, Dr. J. W. Bride, Dr. E. Vipont Brown, Dr. A. W. Berry, Mr. J. G. Clegg, Dr. M. M. Collins, Dr. T. A. Goodfellow, Dr. F. A. Hogben, Dr. J. C. Jefferson, Dr. R. E. Lane, Dr. G. J. Langley, Dr. P. G. McEvedy, Dr. J. Ramsay, Mr. J. H. Watson, and Mr. Harry Platt (acting local honorary secretary). There were also present as guests Professor A. H. Burgess, President of the British Medical Association, Professor H. S. Raper, Professor A. Ramsbottom, Professor E. D. Telford, and Dr. Catherine Chisholm. After "The Health of the King" had been honoured, Sir StClair Thomson proposed the toast of "Prosperity to the Society," observing that, though not yet two years old, the membership was rapidly increasing, 120 new life members having been enrolled during the year 1929, and 25 since January 1st, 1930. Mr. Harry Platt followed, saying how greatly honoured Manchester was by having a dinner of the society in that city. Mr. McAdam Eccles proposed the toast of "The Guests," which was responded to by Professor Burgess. A very pleasant evening ended with a conversazione, when old friendships were renewed and fresh ones made.

Maudsley Hospital.

The second part of the thirteenth course of post-graduate instruction at the Maudsley Hospital, Denmark Hill, has now started, and will continue until the end of May. A series of six lectures on the practical aspect of mental deficiency, by Dr. F. C. Shrubsall on successive Tuesday afternoons, began on March 4th, and the first of a series of twelve clinical demonstrations in neurology, by Dr. Golla on Thursday afternoons, was held on March 6th. The first six of these demonstrations are being given by Dr. Golla at the Hospital for Paralysis and Epilepsy, Maida Vale, and the second six, by Dr. F. M. R. Walshe, will take place at the National Hospital for Paralysis, Queen Square. Twelve lectures on morbid psychology will be given by Dr. Edward Mapother, medical superintendent of the Maudsley Hospital, on Wednesday afternoons, from March 12th, and three lectures on therapeutics, by Dr. A. A. W. Petrie, on Tuesday afternoons, commencing March 25th. Two lectures on abnormalities of the fundus oculi will be given by Mr. Foster Moore, on April 14th and 28th, and there will be six lectures on crime and insanity, by Dr. W. Norwood East, on Tuesday afternoons, beginning on April 15th. Six demonstrations in clinical psychiatry will be given by Dr. Edward Mapother on Wednesday afternoons, from April 30th. During May there will be eight lectures on the psychoneuroses, by Dr. Bernard Hart; four lectures by Sir Hubert Bond, on the legal relationships of insanity and treatment; two demonstrations in laboratory methods, by Mr. S. A. Mann; and four lectures, by Dr. Golla, on the pathology of mental diseases, followed by demonstrations of the pathology of

the central nervous system, by Mr. C. Geary. The fee for this part of the course is ten guineas, and inquiries should be addressed to the director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.5.

London Ambulance Service.

The ambulance services which have been controlled by [illegible] as Board and by the various [illegible]me under the direction of the [illegible] on April 1st. These services, together with the London County Council accident service (hitherto administered by the Fire Brigade Committee), will all be under the Central Public Health Committee of the Council, and will be known as the "London Ambulance Service." The service will consist of two sections, one the "Accident Section" and the other the "General Ambulance Section," the latter comprising the amalgamated ambulances of the Metropolitan Asylums Board and the boards of guardians. The fleet of guardians' ambulances comprises 46 vehicles, which it is considered may be reduced to 30. There will be one central call office for both sections, where priority will be given to accident cases.

Ireland.

Orthopaedic Hospital of Ireland.

AT the annual meeting, in Dublin, of the Orthopaedic Hospital of Ireland, Lord Glenavy presiding, the report for 1929 showed that the number of crippled and deformed children treated during the year was 1,666, of whom 1,460 attended the dispensary and gymnasium and 206 were in-patients. The daily average number of in-patients was 71, the highest figure recorded. The out-patient department continued to increase in size and usefulness; many children were cured by manipulation and plaster appliances. Modern equipment was being used in the gymnasium, including an artificial sunlight lamp for tuberculous bone disease and rickets. In moving the adoption of the report His Excellency the Governor-General remarked that the hospital had been treating deformed children for more than half a century. An effort was being made to provide an open-air extension outside the city, and the fund for this purpose was steadily increasing. He appealed for support in establishing a country home for the hospital. Dr. M. J. Russell, medical officer of health for Dublin City, said that, in spite of all the houses that had been built in and around Dublin, there were more insanitary rooms and dwellings in that city to-day than ever before. Wealthy employers should be asked to build more houses for their employees in order to relieve the municipality.

Free State Census Returns.

According to a report of the *Census of the Irish Free State*, 1926, volume v, the birth rate was normal compared with that of twenty-six countries; the number of children under 15 years of age was also normal, but there was an extraordinary number of orphans and widows, although marriages were comparatively fewer. In spite of larger families the Saorstat appeared exactly half-way down the list of twenty-seven countries as regards the number of children under 15, estimating per 100 of the population between the ages of 15 and 65. Later marriages explained the comparatively higher death rates among parents of young children. Fatherless children exceeded motherless by about 13,000. The proportion of motherless children was greater in the country than in the towns, the reasons being presumably that mothers were older in the country, and fewer motherless children were sent to town orphanages. Low death rates of elderly females and late marriages among males accounted for the large number of widows. In 1926, for every 1,000 of the population between the ages of 15 and 65 there were 74 widows, compared with 65 in England and Wales. The number of persons of 65 and over was also higher—63 per cent. higher than in England and Wales, twice as high as in the United States and Australia, and nearly three times as high as in South Africa. Old age pension schemes were a heavier burden than in any other country.

India.

Child Welfare in the Central Provinces and Berar.

THE immensity of the problem of decreasing the mortality of children in the Central Provinces and Berar is indicated by the fact that nearly one-third of the total mortality of this district in 1928 was due to infants dying under the age of 1 year. This infant death rate of over 238 per 1,000 births was again higher than that in any other province in India. Strenuous efforts are being made to induce a better state of things, and in the annual report for 1928 Major C. M. Ganapathy, I.M.S., director of public health for the Central Provinces, mentions that fourteen new infant welfare centres were established, bringing the total of these institutions to thirty-five at the end of that year; the establishment of additional ones is contemplated. A nursery school was opened in Nagpur to continue the care of children from infancy until the school-going age, and to maintain continuous health supervision. At some of the infant centres arrangements are in force for training native midwives, who are paid for attending the classes; they subsequently enter for examinations, on passing which they are registered and receive certificates. In the year under review eighty-eight midwives were being so trained, and it is hoped that the scheme will extend considerably. Ante-natal clinics have been instituted in the centres wherever medical supervision can be obtained. In order to meet the demand for trained health visitors to take charge of these centres a well-equipped health school under medical control was opened in August, 1928. Health propaganda work was continued throughout the year, and baby weeks were organized in several towns. A large number of municipal committees gave financial and other support to women engaged in conducting labour cases and visiting houses where children had been born. Important factors in infant mortality are recognized as being ill-informed interference by untrained midwives and the lack of proper post-natal care; it is believed that the preventive measures being taken will soon make their influence felt.

The Extension of Medical Treatment in Madras.

A triennial report of the working of the civil hospitals and dispensaries in the Presidency of Madras has been received, covering the years 1926, 1927, and 1928; attention is drawn in it to the considerable progress that has been made in the scheme of subsidizing medical relief in certain rural areas which were out of the reach of existing hospitals and dispensaries, and so had no provision for medical aid, the inhabitants being dependent upon unqualified village doctors and quacks for treatment. In 1925 the Government sanctioned the establishment of 235 rural dispensaries, and 164 additional ones were opened during the period under review. District medical officers inspect these dispensaries periodically and report any defects in their working. The scheme for the training of dhais (native midwives), which was devised to reform the uncleanly and dangerous methods of barber-midwives practising [illegible] has been another noteworthy feature of the [illegible] tioned in 1926, it has enabled fifty-eight dhais to be trained and certified, and arrangements are now being made for the employment of first-class midwives in rural dispensaries, so as to abolish the deplorable conditions which have hitherto attended the confinements of women in these rural areas. The subsidy originally granted to the rural medical practitioners who were appointed to conduct this dispensary work was found to be inadequate, and several dispensaries had to be closed. Their financial support has now been increased, and it is probable that the scheme will be extended before long and considerably improved. The Government has decided to introduce compulsory medical examination in the case of all pupils studying in recognized secondary schools and school departments, and to remodel the present hospital in Madras; details of what has been accomplished already in this respect appeared in the *Journal* of January 25th (p. 168). Antirabic treatment has been extended, and provision made for dental treatment. Additional financial support has been given to leprosy institutions by the British Empire Leprosy Relief Association and the Govern-

ment. Numerous educational lectures, illustrated by lantern slides and cinematograph films, have been delivered in the Presidency, and pamphlets have been distributed dealing with hookworm infection and the dangers of soil pollution. Considerable improvements have resulted in tea, coffee, and rubber estates, but further work is still needed to bring their sanitary conditions up to the modern standard. Major-General J. W. D. Megaw, I.M.S., Surgeon General to the Government of Madras, who compiled the report, expresses gratification at the steadily progressing development that is evident in many branches of medical work in the Presidency, but he is dissatisfied with the standard of efficiency in some of the hospitals, and doubts whether the utmost is being made of what facilities are available. He urges that more attention should be paid to improving the existing institutions, in view of the large sums which are being spent on medical relief and education.

In his report of the King Institute of Preventive Medicine, Guindy, Madras, for the year ending March 31st, 1929, the director, Dr. C. G. Pandit, publishes an interesting table showing, in six specified districts where cholera was epidemic, the relation between the incidence of this infection in patients who had been inoculated previously by cholera vaccine, and those who had not been so treated. It is made clear that the adoption of this measure reduced the total number of attacks to nearly one-tenth in the inoculated, as compared with the remainder, the appropriate correction having been made in respect of the relative numbers treated in each group. Most of the deaths in inoculated patients were found to occur before the fifth day—in other words, before the maximum degree of protection had had time to develop. The figures indicate, therefore, that vaccine treatment gives an almost perfect immunity against cholera if use is made of it before infection occurs. Other vaccines issued by the Institute include influenza vaccine, but, in this case, the director reports that neither its value as a prophylactic nor as a curative measure has been convincingly demonstrated, and there has been a marked fall in its popularity. There has been a general increase in the demand for a puerperal vaccine composed of different strains of streptococci and *B. coli*. An extended trial of it at the Government Hospital for Women and Children gave very promising results, both as a prophylactic and as a curative, and requests for it are now being received from institutions outside the Presidency. Investigations have been conducted by the staff of the Institute in respect of various epidemics of cholera and typhoid fever.

Treatment of Leprosy in Burma.

The measures taken to deal with leprosy in Burma consist at present of treatment in voluntary leper asylums, Government wards attached to these asylums, and in outpatient departments. There are five leper asylums in Burma; two special leprosy clinics—one at Rangoon and another at Mönywa; a leper clinic at the latter place; and a skin clinic at Mandalay for the outdoor treatment of this disease. In his triennial report on the hospitals and dispensaries in Burma for the years 1926 to 1928, Colonel W. H. C. Forster, I.M.S., Inspector-General of Civil Hospitals, Burma, states that a Government committee has been reviewing the general policy to be adopted with regard to leprosy, and certain proposals have now been submitted. It is suggested that there should be a permanent official committee composed of the Inspector-General Civil Hospitals, the Director of Public Health, and the Director of the Pasteur Institute. Asylum segregation should be abandoned in favour of the creation of "propaganda treatment survey centres," further expenditure on asylum construction being discontinued. Treatment would be placed under the advisory control of this official committee. The Burma Pasteur Institute, which was opened in 1915, has among its other duties the task of supervising the treatment of leprosy in asylums, and has prepared, year by year, large quantities of hydnocarpus oil for this purpose. A few cases of this disease have been treated at the Institute, with the object of testing the material so prepared, and various new methods have been examined as they appeared. Alepol is now being made up in a solution suitable for injection and issued to asylums which have reported favourably on its use.

Correspondence.

CHOLECYSTITIS AND COLITIS.

SIR,—The paper on colitis by Dr. H. L. Tidy in the *Journal* of January 25th (p. 135) was most interesting. There is, however, a condition which I pointed out some years ago that is a provocative cause of mucous colitis—namely, chronic cholecystitis with or without gall-stones.

In making an analysis of our series of cases, we found that 20 per cent. had a history of mucus in the stools. Of these, 65.2 per cent. have been entirely relieved of their so-called mucous colitis by the removal of the gall-bladder.[1] The interesting thing that developed in connexion with this study was that in all these cases which showed a mucous colitis we cultured a staphylococcus from the wall of the gall-bladder.

Some years ago a patient, who had had a colostomy done by a London surgeon for the relief of colitis, presented herself some eighteen months afterwards in the hope of having the colostomy closed; but as mucus was still pouring, not only from the colostomy wound, but the rectum as well, and as there was evidence of a marked ulcerative colitis, I removed the gall-bladder on the chance that it might be one of these infected ones, as she showed some evidence of gall-bladder disease. The mucous colitis cleared up in three months, and then the colostomy was closed.—I am, etc.,

Toronto, Feb. 14th. F. N. G. STARR.

THE SIGMOIDOSCOPE IN COLITIS.

SIR,—The arguments for and against the use of the sigmoidoscope in conditions of colitis have interested me very greatly. This instrument has been used as a routine by us during the last eighteen months to assist in the elucidation of inflammatory conditions of the lower bowel, in both the acute and chronic stages of the disease. In a series of over 500 sigmoidoscopic examinations we have not seen any ill effects result from its use, either during its passage through the sphincter or on its further progress up the rectum and pelvic colon.

In Egypt, where symptoms of colitis may be produced by widely different causes, ranging from a bacillary dysentery infection to a bilharzial infiltration of the mucosa of the lower bowel, it is especially important to view the diseased area, a short visual examination often being sufficient to allow of an accurate diagnosis to be made of the etiological factor responsible for the symptoms of the colitis. It is a well-known fact that in bacillary dysentery it is often impossible by laboratory methods to isolate the specific organism after the first week or so of the onset of the disease. It is in such cases that we have found the assistance of the sigmoidoscope to be invaluable, the appearance of the lesions through the instrument being highly characteristic, and allowing accurate diagnosis in cases which otherwise would have remained unclassified.

In a series of cases of acute inflammation of the large gut recently investigated by us, laboratory examination failed to isolate the causative organism in 39.6 per cent., due to the patient's late arrival for treatment, most of them being admitted in the second week of the disease; yet in these laboratory negative patients typical bowel lesions of bacillary dysentery infection were seen through the sigmoidoscope in all except 7 per cent. This allowed us to commence treatment without further delay, confident that we were not dealing with some other specific bowel condition probably requiring an entirely different line of treatment. We have also obtained most valuable information about the progress of healing of various bowel lesions under different methods of treatment.

These facts not only justify the use of the sigmoidoscope, but make its employment an essential procedure in the routine examination of cases with symptoms indicating an inflammatory condition of the colon where the diagnosis is in doubt.—I am, etc.,

THE APPLICATION OF GAMMA RADIATION TO DEEP-SEATED TUMOURS.

SIR,—In the application of gamma radiation to deep-seated tumours the use of two or more convergent beams so adjusted as to intersect within the tumour has been tried. I suggest in what follows a mode of application which appears to possess certain advantages, and which, so far as I know, has not hitherto been tried.

Only one beam is required, but this beam is caused to describe continually a conical path, the apex of the cone being within the tumour. Thus the radiations reaching the tumour are virtually focused in the tumour, in the sense that this becomes the *region of maximum radiation*. As the beam sweeps out its conical path its track where it traverses the surface of the body approximates to a circle of entry. The beam traverses this circle in one revolution. It follows that the risk of surface burns must be much less than if a fixed beam—or two or more such fixed beams—are employed. This reasoning applies also to risk of lesions within the body of the patient. In fact, the concentration is obviously a maximum within the tumour, and falls off rapidly in the surrounding tissues. The fact of continually changing inclination of the rays within the tumour might be expected to be in itself advantageous. Of course, the use of two or more such beams, suitably spaced around the cone of revolution, would be admissible.

A very simple mechanical arrangement will suffice to realize this mode of application of gamma radiation. The drive may be purely mechanical or electrical, and the whole apparatus carried on a suitable stand, combining steadiness with easy adjustment of the cone of radiation. It will be evident that the convergent rotating beam may be caused to describe any path called for by the extent and form of the tumour. A central rotating cam of the required form and dimensions would suffice for this purpose.—I am, etc.,

MORTALITY FROM GASTRO-ENTEROSTOMY AND PARTIAL GASTRECTOMY.

SIR,—I feel I cannot let pass without comment the report of the collective investigation into the after-history of gastro-enterostomy published in your issue of February 22nd (p. 348). When this investigation was first suggested it appeared to many that the results were not likely to represent the true state of affairs as accurately as the records of hospitals with an adequate follow-through system, and, furthermore, there was every probability that the errors might be large enough to render the findings of the investigation totally misleading. We are not told what percentage of the results were obtained from such hospitals, but it is certain that many large groups of statistics were withheld on this account.

That these fears were not unfounded appears to be shown by the mortality figures in Table XXVI. Here the percentage of deaths from posterior gastro-enterostomy combined with local treatment of the ulcer is 4.6; from partial gastrectomy 6.0; from posterior gastro-enterostomy without interference with the ulcer 11.4. Now there are few surgeons with considerable experience of partial gastrectomy (even including those who do not limit the operation to the more extensive and severe cases) who would care to claim such a low figure, and yet these results are supposed to represent the average results which might be expected at the hands of the average operator. I believe the explanation can only be either that the method of investigation adopted has in some way produced an unconscious selection of results, or that in an undue proportion of the cases there were very limited resections, such as pylorectomies, performed by especially skilled operators. The 11.4 per cent. mortality for simple posterior gastro-enterostomy is, on the other hand, still more difficult to explain. Let us allow that this group includes a large number of cases in which the omission of local treatment was due, not to the routine of the surgeon concerned, but to the fact that the ulcers were particularly serious, of great extent, and inaccessible, and still a mortality of over 10 per cent. appears stupendous.

I can see no explanation of such a figure except as the result of the unconscious selection of cases already referred to. It is only natural that such selection would act in reverse ways when it came to the consideration of an extensive operation like partial gastrectomy, performed too frequently as a last resort, where a high mortality would be expected, and the comparatively simple gastro-enterostomy, where a fatality is unexpected, so that the occasional deaths attract an undue amount of attention and remain deeply impressed upon the memory of the doctor.

As an advocate of partial gastrectomy I should be gratified if I could convince myself that the figures given were even approximately correct. My own figures, published elsewhere, over a series of 150 of each type of operation are 8.5 per cent. for partial gastrectomy, and less than 1 per cent. for gastro-enterostomy, and they have of necessity made me a hesitating and half-hearted advocate of what I think otherwise is a thoroughly reliable operation. Discrepancies such as these obviously cannot be lightly passed over as errors of observation.

As a further example of the difficulty of interpreting the results of the investigation I would mention Table III of the interesting series of hour-glass contraction of the stomach. As I understand this term, it should be limited to real fibrotic stricturing, and not applied to mere muscular spasm, which may produce very similar radiograms. Eight of the 65 cases were treated by "posterior gastro-enterostomy and excision of ulcer"; this makes one suspicious that cases of spasmodic contraction have not been excluded, for it is almost impossible to excise these ulcers without performing at least a sleeve resection of the stomach—one type of partial gastrectomy.

The cynical aphorism, "statistics may be made to prove anything, even the truth," is frequently on our lips in these days of biomathematics; but I am apprehensive that the truth has not been reached in this investigation, where the data have been collected from diverse sources uniform neither in method nor interpretation.—I am, etc.,

NORMAN C. LAKE.

London, W.1, March 1st.

*** A review by Lord Moynihan of the results of the collective inquiry appears at page 458 this week.

DIAGNOSIS OF PULMONARY TUBERCULOSIS.

SIR,—Dr. Arnott Dickson, in his lecture on the diagnosis and treatment of pulmonary tuberculosis, states that "the evidence should be strong before a chest case with definite physical signs and sputum is accepted as tuberculous in the consistent absence of the tubercle bacillus." In view of this pronouncement I venture to draw attention to some methods of obtaining a more reliable specimen of sputum than is often presented to us. In a short communication entitled "The early detection of tubercle bacilli in sputum" (*Journal*, 1928, vol. i, p. 627) I described several methods by which I had obtained a *good specimen with positive* results, when with previous specimens the results had been negative. The details will be found in the paper referred to, but the main points, in order, are coaxing the patient to cough out into a basin, and *preferably with the mouth* wide open; the sniffing of the vapour of volatile mustard oil (a few drops in the bottom of a six-ounce bottle warmed over a spirit lamp) to excite cough; the intralaryngeal injection, by means of a *laryngeal syringe*, of a weak solution of sodium bicarbonate to which is added a little hydrogen peroxide, or the transnasal instillation of the same liquid (with the head thrown back while about half a drachm is gently *syringed through the nose* and the patient pants in and out through the mouth, avoiding swallowing); the catching of a patch of sputum on the laryngeal mirror; or the administration of small doses of potassium iodide for a few days.

The practice of these procedures will, I am sure, diminish the number of cases of "consistent absence of the tubercle bacillus," and justify a prompt and confident adoption of the appropriate treatment.—I am, etc.,

JAMES DUNDAS-GRANT.

London, W.1, March 3rd.

SIR,—Dr. Dickson's lecture, which was published in the *Journal* of March 1st (p. 376), is remarkable in compressing the essentials of his subject into the briefest possible space and is, in my humble opinion a model of its kind. It should prove helpful to those whose days are devoted to tuberculosis work, as well as to the general practitioner

I should like to add two simple points in clinical examination which I do not remember to have seen in print, and which I have found helpful in my work as a tuberculosis officer for the past fourteen years.

The first point is that the patient should always be asked to breathe through the mouth during the examination. I have the patient seated on a stool, the back straight, the knees together, and the hands resting on the lap. The examiner's hands are placed flatly and firmly one on either side of the chest, and the patient is asked to take deep breaths in and out through the mouth. The difference in movement between the two sides is then very evident. Compare this with the same movements when nose-breathing is practised and the change will be manifest—indeed, the alteration in expansion of the two sides may even be reversed. In auscultation also mouth-breathing gives very much clearer breath-sounds than nose-breathing, and a cough, followed immediately by a deep inspiration through the mouth, brings out the finest crepitations, even in a very early case. This is not nearly so marked in nose-breathing, in which the sounds are much more muffled.

The second point is that, in percussion (and I agree with Dr. Dickson that very light percussion is essential), the plexímeter finger should be pressed very firmly against the chest wall. In this way as much (or more) can be ascertained from the touch of the plexímeter finger as from the sound of the percussion note; but only if the plexímeter finger be in the most intimate contact with the chest wall.

I am glad to learn that Dr. Dickson finds real help from Verne's photometric test. I have gained more assistance from this test, both in diagnosis and in prognosis, than from any other extraclinical method, save only a positive sputum.—I am, etc.,

Lewisham, S.E., March 1st. ROSE JORDAN.

OESOPHAGEAL OBSTRUCTION IN CHILDHOOD.

SIR,—In the December number of the *Archives of Disease in Childhood* (1929, vol. iv, No. 24, p. 347) there was published a very interesting and important article by Drs. Sheldon and Ogilvie on obstruction of the oesophagus in childhood. Since no correspondence is published in the *Archives*, and in view of the editorial remarks in your issue of January 4th (p. 28), I should be obliged if you would grant me space to make some comments on their paper.

The authors have collected and discussed twelve cases of oesophageal obstruction which have been treated in the Hospital for Sick Children, Great Ormond Street. Although some were originally diagnosed as cardiospasm or achalasia of the cardia the authors consider that they were all cases of congenital stenosis of the oesophagus. It seems to me, from the descriptions given in the article, that the diagnosis of some of the cases and the conclusions based upon them are open to serious criticism. Probably the authors have much more information at their disposal, and I quite appreciate that exigencies of space make it difficult to give a really full description of twelve cases, but it would certainly have added greatly to the value of the paper if fuller details had been published.

I venture to assert that there are only two certain ways of diagnosing congenital stenosis of the oesophagus, one being oesophagoscopy and the other a post-mortem examination. Apparently not one of these patients was examined with the oesophagoscope, and of the four on whom necropsies were performed, one, Case 10, showed no abnormality of the oesophagus. From this case the authors arrive at a conclusion which I find it very difficult to accept. Seeing that they take it as a typical example of the whole group, it may be profitable to discuss it at some length.

They consider that the child had a stenosis of so severe a degree that vomiting was present from birth. The symptoms continued until she was more than 3 years old, and yet, when she died a year later, there was not the slightest trace of any abnormality in the oesophagus. They assume that as a result of maintaining a fluid diet, the stenosis underwent a spontaneous cure, and they give various reasons for this assumption. They state that they can find no record in the literature of a case of achalasia occurring in the middle of the oesophagus, nor at the junction of the middle and lower thirds. I think it is safe to suggest also that they have found no record of the spontaneous cure of a proved case of congenital stenosis. Incidentally, I have had a child under my care with obstruction in the middle of the oesophagus, clearly demonstrated by *x*-ray screening, but undoubtedly due to spasm, as proved by negative findings at oesophagoscopy and by variation in the site of obstruction.

Secondly, they state that in achalasia there is always hypertrophy and usually dilatation of the muscular wall of the oesophagus, and in order to ascribe Case 10 to this condition, it is necessary to assume that achalasia (and, I suppose, spasm) can undergo spontaneous cure, with disappearance of the hypertrophy and dilatation, under treatment by fluid diet alone. I find this an easier assumption than theirs. In congenital narrowing, as distinct from the membranous type of obstruction, the essential lesion is a definite deficiency of tissue; it is difficult to believe that the maintenance of a fluid diet will lead, in the course of twelve months or less, to a production of new tissue, and will do so with such exactitude that no trace of the original deficiency can be found! In any case of oesophageal obstruction of long standing there must be some hypertrophy, and there may be dilatation (as seen in their radiograms), so the authors will have to accept its disappearance not only as a possibility, but as a fact.

Among the cases collected in my paper on this subject is one originally reported by Greig. This patient lived to the age of 82 on a fluid diet, but it did not cure her stenosis. The balance of evidence in Case 10 seems to be very much in favour of spasm as the cause of the obstruction. In some of the others also, I think that, on the published details, there is considerable doubt about the diagnosis.

As I said at the beginning of this letter, the paper by Drs. Sheldon and Ogilvie is an important one, and in my opinion the most valuable part of it is the strong evidence which the authors produce that non-organic obstruction of the oesophagus can occur in infancy—an opinion which is fundamentally different from the one they have formed.—I am, etc.,

London, W.1, Feb. 26th. C. C. BEATTY.

ANAESTHETICS FOR SHORT OPERATIONS.

SIR,—As a teacher of dental anaesthesia I feel that Dr. H. H. Brown's letter in the *Journal* of February 22nd (p. 352) requires some comment. While it is quite possible that the state of analgesia described can be obtained by Dr. Brown and others of great experience, to advocate the routine use of chloroform in dental work, much less its use in the ordinary dental chair, would have one unfortunate result—namely, to increase the work of the coroners. Perusal of both the medical and lay press shows that most of the fatalities in anaesthesia have been where chloroform has been given, and many of these disasters occurred in dental cases. The wholesale adoption of the method advised by Dr. Brown would be contrary to the experience of most teachers and anaesthetists. I may add that I am by no means biased against the use of chloroform in suitable cases and, in fact, use more of it than many of my colleagues.—I am, etc.,

Liverpool, Feb. 27th. G. F. RAWDON SMITH.

SIR,—I have been much interested in Dr. H. Marcus Bird's article on anaesthesia for short operations on children, published in the *Journal* of January 25th (p. 147), and also in the subsequent correspondence.

I have during the last two years performed the operation of tonsillectomy, using the guillotine method, on 1,495 children at the Manchester Northern Hospital. In all these cases somnoform has been the anaesthetic used. This is a mixture containing ethyl chloride 83 per cent., methyl chloride 16 per cent., ethyl bromide 1 per cent. It has been administered by the closed method—3 c.cm. of the mixture I find is sufficient for children up to 12 years of age. Ethyl chloride alone does not appear to be taken so easily, and the patient does not appear to be so comfortable after the operation. Complete anaesthesia is induced in about fifty seconds and remains for about forty seconds, which time is ample for removal of the tonsils and curetting the adenoids.

Dr. VERNON DAVIES said he had placed on the paper amendments with the definite object of removing voluntary patients from any interference by the Board of Control. He recognized that the Board at present had a large number of voluntary boarders under its care, but he suggested that the bill should change the whole outlook on the question. Its whole object was to induce voluntary patients at the earliest possible stage to submit themselves willingly to treatment with the knowledge that no stigma of certification or of lunacy would attach to them. Once the Board of Control came in, and once a man knew that if he went to a general hospital or a special hospital as a voluntary patient his case would be notified to the Board of Control, the association of lunacy would immediately be brought into the patient's mind, and into the minds of his friends. Another aspect of the case was that of suicide. People on the borderline of suicide would not submit themselves to treatment on account of the fear of being classified as mentally unfit. Suicide increased practically every year. The people liable to it were unemployed and short of money, they had domestic worries, and could not face the outlook. Dr. Robertson of the University of Edinburgh had recently declared that the stigma of certification prevented poor people on the borderline from submitting themselves to the present method of treatment under voluntary control, and they therefore became suicides. Dr. Davies declared that if his amendments to cut out the Board of Control were accepted a large number of these persons would put themselves under treatment on the first sign of early mental worries. If, however, the doctor said, "You have been coming to me for a month and you are no better, so it is essential that you should come to the hospital, but understand that if you come in you must sign an application form, and that means that you cannot leave this place for seventy-two hours without my permission; it also means that I shall have to notify the Board of Control, and that one of these gentlemen may come and inspect you." In that case the patient would say, "I am not going in. I am not going to have even the suspicion of a Commissioner of Lunacy coming to see me." Then the whole purpose of the bill would be lost. People would not come for treatment in the early stages. They would become suicides, or be certified.

Sir BOYD MERRIMAN supported Mr. Greenwood, and thought it would be a profound mistake to do away with the responsibility of the Board of Control with regard to voluntary patients. It was essential that there should be some control of these patients.

Miss SUSAN LAWRENCE said it was erroneous to assert that at present the Board of Control dealt only with lunatics. Mental deficiency of voluntary boarders and certified lunatics were all under its control. Persons with sufficient money to be treated privately did not now complain, because they could be classed as voluntary patients under Section 229 of the Lunacy Act. These patients at present could be received at a licensed house if two of the Commissioners consented in writing Decent treatment and safety of such patients was a responsibility of the Board of Control, and the patient had to give twenty-four hours' notice before leaving. The bill was extending the same treatment to rate-aided voluntary patients. There were two hospitals for the treatment of early mental deficiency—the Maudsley Hospital, and another established under special Act by the London County Council. These hospitals took lunatics. Some of their voluntary patients passed beyond that stage and were certified in the hospital. Yet there was no reluctance to enter the Maudsley Hospital or the other registered hospital. The voluntary boarders outnumbered the certified boarders. The early mental and severe mental cases required the same doctors and the same staff. If early cases were put in a special asylum they would not get good expert service. All doctors were the same. In their heart of hearts they loved a severe case, and experts in lunacy would not be secured unless they were in contact with the deeply mentally afflicted. The House could do a great deal of good by the existing machinery. If in the quest for perfection they rejected it they would lose this bill. In the present session there was no time to do more than was proposed in this bill.

Mr. RHYS DAVIES said it was not generally understood that the rich voluntary boarder was under the control of the Board of Control. It had been assumed that it was the institution, and not the individual, which was under that control. The bill would definitely put the voluntary boarder, for all practical purposes, in the same category as the registered lunatic.

Dr. MORRIS-JONES remarked that, on second reading, the bill received universal assent, and was carried without a division, but if the amendments now under discussion were passed they would jeopardize the bill.

Mr. SOMERVILLE HASTINGS thought that people suffering from mental disease ought to be under the supervision of the Board of Control. This issue was in danger of confusion with the question whether the hospitals or institutions in which early cases were treated should be definitely connected with lunatic asylums. That point was very doubtful, and it was a great mistake to bring it up when discussing the supervision of the Board of Control.

Mr. RICHARD RUSSELL thought that a great deal of the opposition was based on purely sentimental reasons on account of the name "Board of Control." He suggested that the name of the Board might be changed when it was dealing with the voluntary patient.

Mr. KINLEY'S amendment was then rejected without a division. On the motion of Mr. GREENWOOD, and in fulfilment of a promise given by him on the first sitting of the committee, the final words of Clause 1, Subsection (1) were amended. As they originally appeared they provided that a voluntary patient might be received "with the consent of the Board into single care." Mr. Greenwood moved to delete these words and to insert instead "into the charge as a single patient of a person so approved, and any approval under this section may be granted subject to such conditions as the Board think proper and may be revoked at any time." The amendment was accepted without discussion.

The committee passed to the discussion of Subsection (2) of Clause 1, which provides that any young person under 16 may be admitted for treatment for mental disorder on a written application from the parent or guardian accompanied by a medical recommendation, and shall be received as a voluntary boarder.

Mr. WOMERSLEY moved to leave out the word "sixteen" and to insert instead "eighteen." He said the amendment was put down on behalf of the Municipal Corporations' Association. The first steps to the bill proposed an age of 18 years, but the House of Lords had substituted 16. Mr. GREENWOOD said the Lords had substituted 16 years, this being the age at which a person might legally marry. He would have preferred 18, but did not wish to reopen the question, and thought the Lords' amendment should be accepted. By 33 votes to 4 the committee agreed that "sixteen years" should remain part of the clause.

In accordance with an amendment by Dr. Fremantle, previously carried, the word "illness" was substituted for the word "disorder" in Subsection (2), and "patient" for "boarder." In Subsection (3a), dealing with the qualification of the person who should sign the medical recommendation for a juvenile voluntary boarder, Mr. CHARLES WILLIAMS proposed to leave out the words "who shall be either the usual medical attendant of the person to whom the application relates, or a person who has been approved for the purpose of making such a recommendation either by the Board of Control or by the local authority within whose area the said person then is."

Mr. GREENWOOD said the local authority referred to in this amendment was that of the county or county borough. The words had been inserted by the House of Lords after a discussion on the fundamental question of safeguards for patients, and the Government had agreed to them to provide added protection for voluntary patients. As the proposal originally stood, the recommendation was to be signed only by a registered medical practitioner. The officials through whom the county or county borough might act would be a matter of administrative practice.

Dr. DAVIES said the council would appoint a medical man specifically for this purpose. Mr. WILLIAMS withdrew his amendment.

In the same subsection, on the motion of Captain GUNSTON, the words "medical practitioner" were substituted for the words "a person who has been approved." Dr. FREMANTLE also moved to provide that this medical practitioner should be approved both by the Board of Control and the local authority, instead of by either, as the bill contemplated. He said he proposed this at the instance of the Council of Mental Hygiene. The medical superintendents in their association felt that many local authorities might possibly approve some medical man who was not really fit for the job. It was therefore felt that the Board of Control should have a share in the appointment.

Mr. GREENWOOD said that he dare not ask the county councils and the county borough councils to submit to this. They would be up in arms. Dr. FREMANTLE thereupon withdrew his amendment.

In Subsection (5) of Clause 1, which provides that a voluntary patient must give seventy-two hours' notice in writing of his intention to leave, Dr. FREMANTLE proposed to substitute "three clear days" for the words "seventy-two hours." He said this was brought forward as the considered opinion of the medical superintendents, and by the Medical Women's Federation as well. It was for the convenience of the patients in order that adequate arrangements might be made for them by their relatives and friends.

Mr. GREENWOOD said the days would always end at midnight, which would be no more convenient than the expiration of seventy-two hours. Under the present law the period was twenty-four hours, which was too short to make adequate arrangements for the care of a person who desired his release. A number of people thought seventy-two hours was too long, but Dr. Fremantle's amendment would make the period still longer. The recommendation of seventy-two hours was made definitely by the Royal Commission on Lunacy. Dr. FREMANTLE withdrew his amendment, as did Dr. DAVIES another amendment on the same section, which proposed to refer to the patient's "desire" to leave the institution instead of his "intention."

Sir BOYD MERRIMAN moved to leave out the words:

"If any voluntary boarder by or in respect of whom such a notice has been given is not allowed to leave the institution, hospital, home, or place at the expiration of the notice, he shall be entitled to recover as liquidated damages from the person in

charge ten pounds for each day or part of a day during which he is detained."

He said that if a really serious wrong was perpetrated and a man was detained who ought never to have been so detained it was preposterous to say in advance that the damages were to be limited to £10.

Mr. GREENWOOD said this was the same provision as in the principal Act. He was inclined to think that £10 was an unnecessary limit in a case of wrongful detention. He was therefore willing to take out the lines as suggested by Sir Boyd Merriman.

Mr. RHYS DAVIES inquired what redress a patient would have, if the amendment were accepted, against those who had detained him against his will.

Sir BOYD MERRIMAN said the common law allowed an action for damages.

Mr. COVE suggested that the subsection should be amended to provide that the damages should be not less than £10 a day.

Mr. SORENSEN suggested that some specific provision should be retained in order to draw attention to a right that might otherwise be overlooked.

Sir BOYD MERRIMAN contended that to make the £10 penalty a minimum figure was overlooking the fact that a rantankerous patient might acquire a technical right of action because he had been detained for an hour over the seventy-two hours. A technical case might also arise where a man who was detained over the seventy-two hours was eventually certified as a lunatic. Although technically wrongfully detained, everybody would agree that it was in his own interests that he should be detained.

On a division the committee by 21 votes to 13 deleted the words "if any voluntary" at the beginning of this proviso, which is now regarded as excised from the bill. The committee then adjourned until March 4th.

The discussion was resumed on March 4th. On Clause 1, which gives power to receive voluntary boarders, Mr. C. WILLIAMS moved an amendment providing that a voluntary boarder should leave the institution, hospital, home, or place on receiving from the person in charge seventy-two hours' notice in writing requiring him to leave, or, if he was a person under 18, on such notice being given to his parent or guardian.

The amendment was negatived.

Dr. FREMANTLE moved an amendment providing that the person in charge should have power to admit or to discharge a voluntary patient and to take steps to have such patient dealt with under the principal Act, or under Section 5 of this bill, with the approval of the Board of Control. He said that, although his amendment included the point dealt with in the previous amendment, it also dealt with an entirely different matter. He had been asked to put forward this amendment by the Royal Medico-Psychological Association, the Medical Women's Federation, and the Council for Mental Hygiene. The object was to give a definite status to the person in charge.

Mr. GREENWOOD could not accept the amendment. It meant that the person in charge was to be at liberty if he so wished to act quite irrespective and independently of any arrangements that might have been made by the authority responsible for the institution.

The amendment was rejected by 27 votes to 3.

On the question that Clause 1, as amended, should stand part of the bill, Mr. C. WILLIAMS asked if the medical members of the committee were satisfied that the position of the patients was now sufficiently safeguarded.

Dr. VERNON DAVIES replied that, speaking as a medical man, he thought the amendments inserted had definitely strengthened and improved the clause. Although the clause perhaps did not go as far as one would wish, there was every reason to congratulate the committee on the changes which had been made. Sir BOYD MERRIMAN also expressed the view that the clause had been improved by the insertion of the amendments. The clause was then added to the bill.

Clause 2 provides for notice of the reception, death, or departure of voluntary boarders, and for boarders who become incapable of volition.

Dr. VERNON DAVIES moved the omission of Subsection (1), which provided that, where a person was received as a voluntary boarder, notice of his reception should, before the expiration of the day next following the day on which he was received, be sent to the Board of Control by the person in charge. He said that the obligation to give notice to the Board of Control would prevent voluntary patients from submitting themselves for early treatment, as the association of the Board of Control with lunacy was a very strong factor in the minds of these people. They might be wrong, but the idea was there, and it had to be reckoned with.

Mr. GREENWOOD opposed the amendment. He said that a long discussion took place on the Board of Control last week, and the committee could not reopen the matter. The subsection was an essential safeguard to the liberty of the individual, and must remain as an integral part of the bill.

The amendment was rejected by 25 votes to 7.

Subsection (3) provides that if any voluntary boarder becomes incapable of volition he shall not be retained as a voluntary boarder for a longer period than one month, but shall, on or before the expiration of that period, be discharged.

Sir BOYD MERRIMAN moved to substitute, for "incapable of volition," the words "incapable of voluntarily submitting himself to treatment." He explained that this was the first of a series of amendments which dealt with an important point which was raised on the second reading. The Minister of Health had indicated to him that he would probably meet this point by drafting an amendment to define the words "incapable of volition," and he (Sir Boyd Merriman) was anxious to hear exactly what the right hon. gentleman proposed to do. The whole committee was aiming at the same object, but to him, as a lawyer, to say that a person was "incapable of volition," even for the time being, was to say that he was completely mad. He was sure that the Minister did not mean that. The intermediate class between the voluntary patient and the lunatic consisted of persons unable to make up their minds to co-operate in their own treatment, and he asked the committee to say so. Under the clause, as he would amend it, the patient whose condition improved could, after a month, be dealt with as a voluntary patient. His objection was to terminology, and not to the substance of Clause 5.

Mr. GREENWOOD thought that too much importance was attached to the form of words. The persons covered by Clause 5 would to-day be certifiable, but with a chance of recovery, and he thought that the term "capable of volition" pretty well expressed what the committee had in mind. He did not think the phrase suggested by Sir Boyd Merriman was sufficient for its purpose. If the term was accepted in Clause 2 it would have to be accepted in Clause 5.

The CHAIRMAN ruled that the decision now taken must affect the whole bill, and the issue could not again be discussed.

Mr. GREENWOOD argued that it would be convenient to keep the phrase "incapable of volition" in Clause 2, but to extend it in the definition clause by some such words as "incapacity to express willingness or unwillingness to accept treatment for mental illness."

Mr. SOMERVILLE HASTINGS thought that Sir Boyd Merriman's amendment improved the bill. It covered two types of patients. The first was the voluntary patient, who suddenly became like a log; the other the individual who temporarily developed an illusion, say, of persecution, which the medical officer believed to be only temporary.

Dr. VERNON DAVIES said there was sane volition and insane volition. The phrase in the bill was too compact. "Incapable of a desire of submitting himself to treatment" was clear, and could only bear one interpretation. Some cases capable of voluntarily submitting themselves to treatment really ought to be certified.

Sir BOYD MERRIMAN thought that the words suggested by Mr. Greenwood met the point he had raised. There was a real practical difference between a man incapable of volition in all respects and only incapable of collaborating in his own treatment. A man might be able to feed himself and manage his affairs, but quite unable to give thought to his own health as a result of mental illness.

Dr. MORRIS-JONES said that medical men of experience in mental work did not like the phrase "incapable of volition," because that was an expression of opinion, and could not be testified to as a fact. It was important that medical men making a recommendation should testify to a fact, not to an opinion.

Mr. GREENWOOD suggested that members should table alternative definitions.

Dr. FREMANTLE suggested that Clause 2 should read, "If any person received as aforesaid becomes at any time incapable of expressing willingness or unwillingness to receive treatment. . . ."

Dr. VERNON DAVIES said the issue involved was so important that discussion should be deferred till the Minister had drafted a definition and put it on paper.

Mr. GREENWOOD thereupon moved that the committee should adjourn till March 6th.

The committee adjourned accordingly.

After-Effects of Poison Gas.

On March 3rd Mr. F. O. ROBERTS, replying to Mr. Lawther and Mr. Shepherd, said that in dealing with individual claims for war pensions, each of which was carefully considered, medical officers of the Ministry of Pensions were always alive to any symptoms or history of gas poisoning. The effects of such poisoning had been the subject of special investigations by medical experts, both on the staff of the Ministry and outside. The conclusions arrived at did not support the suggestion made by Mr. Shepherd that there was necessarily a connexion between exposure to gas and the subsequent development of tuberculosis. In present circumstances he did not think that the setting up of a special commission to inquire into the possibility of tuberculosis developing after years of discharge from war service would be justified. Mr. LAWTHER asked whether, as the War Office

Committee which was considering these claims regarded the setting up of such a commission as necessary in order that the fullest opportunity should be given of reaching an understanding on the matter, the Minister would reconsider his decision. Mr. ROBERTS replied that he was willing to consider any suggestion in reference to the matter. The best medical advice that he could secure had been given to him, and on that he was bound to act. Mr. OLDFIELD asked whether, in view of the great ambiguity which arose in discussing some of these gas poisoning cases, the Minister would always give the benefit of any reasonable doubt to the applicant. Mr. ROBERTS replied that that was already done. Mr. EDE asked if the Minister had consulted the French medical authorities who were in charge of the gas-mixing factories in France during the war, and who held strong views on the question of the delayed action of gas in relation to tuberculosis. Mr. ROBERTS: No, Sir. I have not had a chance of consulting those authorities, but I will certainly take advice about it. Major COHEN asked if the authorities of the British Legion, at Preston Hall, who had made a special study of this question, had been consulted. Mr. ROBERTS replied in the affirmative. He said that he had the report of those experts. He had read it on more than one occasion, and had it in mind when he gave his original answer that afternoon.

Mr. ROBERTS, on March 3rd, told Colonel England that the number of ex-service men who had died from the effects of gas poisoning, and whose disability had been recognized by his department as being attributable to, or aggravated by, war service, during each of the last ten years, could not be given with any degree of completeness, since the effects of gas poisoning would ordinarily appear in the form of specific disabilities of the respiratory organs. Any claim submitted in consequence would be recorded under these disabilities.

Chemical Warfare.—On March 3rd Mr. A. HENDERSON told Sir W. Edge that the Convention prohibiting chemical and bacteriological methods of warfare had been ratified, or definitely acceded to, by Australia, Austria, Belgium, Canada, China, Egypt, Finland, France, Germany, India, Italy, Liberia, New Zealand, Persia, Poland, Rumania, South Africa, Spain, Turkey, Russia, the United Kingdom, Venezuela, and Yugoslavia. The Convention had been signed, but not yet ratified, by Abyssinia, Brazil, Bulgaria, Chile, Czechoslovakia, Denmark, Estonia, Greece, Japan, Latvia, Lithuania, Luxemburg, The Netherlands, Nicaragua, Norway, Portugal, Salvador, Siam, Sweden, Switzerland, the United States of America and Uruguay. He understood that Denmark, The Netherlands, and Portugal intended to ratify shortly. While it was impossible to state precisely the activities of foreign nations in this connexion, many nations were, he understood, continuing research work.

Accommodation for Mental Patients.—Replying to Mr. Sorensen, on February 20th, Mr. GREENWOOD said that representations by local authorities, complaining of unnecessary delay in the sanctioning of plans for new buildings, were frequently made to the Board of Control and other departments concerned, though he had no precise figures. Delays in the past were attributable to inadequate staffs, which had recently been strengthened, and the Mental Treatment Bill contained proposals for the reorganization of the Board to facilitate its operations. He hoped to avoid further delays under the new bill. Mr. CLYNES, on February 17th, told Mr. Ramsbotham that he was advised by the Minister of Health that any persons mentally defective within the meaning of the Mental Deficiency Acts, 1913-27, whether or not they were suffering from the after-effects of encephalitis lethargica, could be dealt with in a certified institution willing to receive them. At present there was an insufficiency of institutional accommodation throughout the country, although if the persons concerned had dangerous and violent propensities the Board of Control had provided accommodation at the Rampton State Institution. He would consider, in consultation with the Minister of Health, whether advice could usefully be given to magistrates on the matter.

Applications for Discharge of Mental Patients.—Mr. GREENWOOD informed Mr. Richardson, on February 27th, that there were objections to the recommendation that Section 79 of the Lunacy Act be posted up in waiting rooms of public asylums, with a view to informing relations and friends of patients of their rights relating to applications for discharge, of which they would have otherwise been in ignorance, but the rules of the Board of Control required the managers of every institution, on the admission of every rate-aided patient, to send a notice embodying the substance of Section 79 to all persons whose names appeared as relatives or friends of the patient on the statement of particulars accompanying the reception order. He would see that this was carried out.

Dismissals under the Board of Control.—Mr. GREENWOOD told Mr. Sorensen, on February 27th, that during 1929 notice from the Board of Control was received of eighteen dismissals and one resignation of officers on the ground of proved ill-usage of patients. He could not say at present the number discharged from licensed houses. The cost of the Board of Control, he told Mr. Richardson, was £84,987 for 1928 and £87,418 for 1929. Sums of £40,506 and £42,849 respectively, representing the cost of State institutions, were included in these figures.

Clinic for Treatment of Rheumatism.—On February 20th Mr. GREENWOOD told Mr. Lewis that, though he would watch with interest the new British Red Cross Society clinic for the treatment of rheumatism, he did not think it necessary at this stage to set up a special body to co-operate with the society. Research was constantly under the consideration of the Medical Research Council, who would acquaint themselves with the results of the new clinic.

Cancer Remedies.—On February 20th Mr. GREENWOOD, in reply to Mr. R. S. Young, said that in judging the value of any treatment of cancer submitted to him the Ministry of Health was guided by all relevant information available, including results in application to specific cases. This was so when the remedy originated outside the recognized medical profession. He promised to inquire into the claim of a Mr. Evans who had supplied to the Ministry of Health in 1923 the names of thirty patients he professed to have cured. Mr. R. S. Young alleged that since that year none of these people had been communicated with by the department.

Welfare Centres and Birth Control.—Mr. GREENWOOD, replying to Mr. E. D. Simon on March 3rd, said that the Ministry of Health had never withheld, or threatened to withhold, grants payable to local authorities in respect of maternity and child welfare work on the ground that medical officers had given information on birth control to women attending the centres.

Administration of Anaesthetics by Midwives.—On March 3rd Mr. GREENWOOD informed Brigadier-General Brown that he had received a resolution from the South Berkshire Women's Unionist Association asking him to give careful consideration to the desirability of authorizing certified midwives to give anaesthetics in cases of childbirth. He understood that the question of giving anaesthetics at the time of childbirth was being considered by the Maternal Mortality Committee, and he proposed to await their report.

Food Value of Milk.—On February 25th Mr. ADAMSON told Mr. Hurd that 20,000 children in 68 schools of the Lanarkshire Education Authority would be included in the present investigation into the value of an additional daily ration of milk in the dietary of the school child. Of these children, 10,000 would receive milk and 10,000 would receive no ration, but would be weighed and measured for comparison. The results of a previous investigation showed that the addition of milk to the diet produced a marked improvement in the physical condition of children of all school ages.

Nystagmus.—Mr. TURNER, replying to Mr. Shield on February 25th, said that in 1928, the last year for which information was as yet available, the incidence of new cases of nystagmus, in proportion to the number of miners employed, was greatest in Ayrshire.

National-Health Insurance.—On February 26th Mr. GREENWOOD informed Mr. Rhys Davies that draft regulations with respect to the issue of certificates for national health insurance purposes by medical practitioners, and the definition of drugs for the purpose of medical benefit, were in preparation. He could not say when they would be before Parliament.

Excessive Prescribing by Panel Practitioners.—Mr. JOWETT, on February 27th, asked Mr. Greenwood whether he would decide not to impose a fine on certain panel doctors referred to in a resolution of the London Insurance Committee. Mr. Jowett summarized this resolution as requesting the Minister to impose a fine of £100 on four panel doctors for prescribing for their insured patients drugs and dressings beyond the average, although the tribunal appointed by him to consider this charge found in no individual prescription evidence of irregularity or extravagance, and reported that these practitioners were actuated by high idealism and had organized an efficient treatment centre in a neighbourhood where the chances of maintaining health were poor, and added to their report a recommendation that any penalty should not be more than a formal one. Mr. GREENWOOD replied: The practitioners concerned have exercised their right to make oral representations on the question what amount of money, if any, should be withheld; and I cannot anticipate the decision at which it will be my duty to arrive after receiving the report of the persons appointed by me to hear these representations. I must not, however, be understood to accept Mr. Jowett's references to the report of the referees in this case as being either a complete or an accurate summary of their findings. Mr. MILLS: Is it not a fact that panel doctors in practically every insurance area are constantly in conflict with these committees?

Bakers' Dermatitis.—Replying to Mr. Cecil Wilson, on February 27th, Mr. CLYNES said that in 1922 there were 102 cases in which bakers obtained certificates of disablement under the Workmen's Compensation Act from certifying surgeons in respect of dermatitis; there were 334 cases in 1926, 275 in 1927, and 389 in 1928. The increase might be due to the new Order which came into force in January, 1923, which relaxed considerably the conditions under which compensation for dermatitis had been payable. The disease became notifiable under the Act on May 6th, 1916. The main precautions were care of the hands and arms and scrupulous personal cleanliness, to promote which a Welfare Order under the Factory Acts, May, 1927, required the provision in bakehouses of washing facilities and prominent display of precautionary notices on the prevention and cure of dermatitis. These provisions had secured improved conditions of work and a wider knowledge of the disease.

Regulations for Safety in Cinematograph Theatres.—Mr. CLYNES told Mr. Ede, on February 27th, that the principal regulations for securing the safety of the public in cinematograph theatres were those made under the Cinematograph Act, 1909. It was open to local licensing authorities to supplement these by special conditions inserted in the licences issued by them, and many authorities did so, though he did not know how many.

Notes in Brief.

During 1926 to 1929 inclusive, 13 children under 14 years of age were certified as having died as a result of vaccination or vaccinia. In view of the fact that vaccination was compulsory no compensation had been paid to parents.

Obituary.

SIR ALFRED FRIPP, K.C.V.O., C.B., M.S., F.R.C.S.,

Honorary Surgeon to H.M. the King; Consulting Surgeon to Guy's Hospital.

WE had to announce last week the death, after a short illness, of Sir Alfred Fripp, sometime Surgeon in Ordinary to the King and to King Edward VII, and for more than thirty years a prominent member of the surgical staff of Guy's Hospital.

Alfred Downing Fripp was born at Blandford, on September 12th, 1865. He was the eldest son of Alfred Downing Fripp, R.W.S., who was the grandson of Nicholas Pocock and the brother of George A. Fripp, R.W.S. This ancestry explains the ardour with which the surgeon collected water-colour drawings. He was sent to school at Blandford; from there, in 1879, he passed to Merchant Taylors, recently moved to Charterhouse Square; here Dr. William Baker was his head master. Fripp already showed his aptitude for sport, playing in the first cricket eleven for three years. Entering at Guy's Hospital in 1884, he became dresser to Mr. Davis-Colley, who thought highly of him; he was captain of both the cricket and Rugby football clubs; he played forward, and was the first to arrange for the good programme which the Rugby club still has. In addition, he was an exceptionally fine swimmer, and was very fond of boating; he hardly ever missed a Henley meeting. He took his M.S. at the University of London, and his F.R.C.S. in 1893. A fellow student, who worked much with him, writes: "I had a deep regard for this happy, broad-shouldered fellow, who worked well and played well." After finishing his house appointment he became demonstrator of anatomy, and was elected assistant surgeon to the hospital in 1897, and, when his turn came, full surgeon, from which post he retired on reaching the age limit of 60 in 1925.

Fripp was a first-rate surgeon. He took infinite pains in examining each case and in judging every patient as an individual; it was a pleasure to see him operate; he was bold, methodical, and careful, without being slow; his cheerfulness and his kindness helped his patients greatly; he always considered sympathetically all the little discomforts which often follow operations, and he had an unusual power of imparting confidence. He quickly became a thoroughly good and popular teacher; students flocked to his out-patients or his wards, for he told them just the points that would be useful to them in practice. Occasionally he contributed a case to the pathological and clinical societies, but he did not write much: his only book was *Human Anatomy for Art Students*, which was written in conjunction with his colleague A. R. Thompson. Fripp always took a pleasure in organizing, and it was he, together with Dr. Lauriston Shaw, who in 1891 amalgamated the various athletic and other clubs at Guy's into one clubs union, to the great advantage of the clubs and the Medical School. This was the first union of its kind. Except that for a short while he was surgeon to the Hospital for Children and Women, Waterloo Road, Fripp was not attached to any other hospital than Guy's.

Just as he was finishing his house-physiciancy a message arrived from Mr. Jalland of York to say that he wanted a locumtenent while he went for a holiday. Fripp had looked forward to a holiday himself, but, on the advice of a member of the staff, he went to do Jalland's work. One evening a call came asking Jalland to go to the barracks. Fripp went in his place, and found the patient to be the Duke of Clarence, who was stationed in York with his regiment; by a strange chance he and Fripp had previously spent an evening together in Cambridge. This led to Fripp's introduction to the late Queen Victoria, to the Prince of Wales (afterwards King Edward VII), and to our present King. In 1897 Fripp was appointed Surgeon in Ordinary to the Prince of Wales, who in 1898 slipped on a staircase and broke his kneecap. His Surgeon in Ordinary was recalled from his honeymoon to be associated with those who had been already summoned to attend the Prince. Fripp was reappointed Surgeon in Ordinary when the Prince became King Edward VII. He held the same appointment, and subsequently that of Honorary Surgeon, to our present King, and that of Surgeon in Ordinary to H.R.H. the Duke of Connaught. He was awarded the C.B. and the C.V.O. in 1902, he was knighted in 1904, and made a K.C.V.O. and a Knight of Grace of the Order of St. John in 1926. His very early association with royalty led to his being nicknamed at Guy's "The Baron," or sometimes "My friend the Prince," for there happened to be at this time a popular play having this title. In 1899 the Prince of Wales was president of Guy's Hospital. Sir Cosmo Bonsor had just been appointed treasurer; he and Fripp worked energetically to form a re-endowment fund, which was necessary owing to the great falling off of the agricultural rents of the hospital. The Prince presided at a festival dinner at which the sum of £114,347 was collected. Ever since this Fripp, who had a remarkable aptitude for raising money for charities, was most hard-working in obtaining funds for Guy's; many very large donations have been due to him, and it was in consideration of all that he had done for the hospital that he was appointed a governor on his retirement from the post of surgeon.

In 1899 Fripp went out to the South African war as surgeon and chief civilian officer of a Yeomanry hospital of 520 beds. For this work he was mentioned in dispatches. His wife went with him, and for her services received the R.R.C. He contributed to this *Journal* in 1900 "Letters from South Africa on Military Hospitals," and on his return to this country he, Sir Cooper Perry, and others were appointed to report upon the military medical service. As a result, an Advisory Board for Army Medical Services was formed, with Fripp as a member. All this meant a long period of very hard and difficult work, into which Fripp threw himself with all his customary initiative and energy. In the great war he was consulting surgeon to the Royal Navy, and many casualties from the North Sea battles passed through his hands. He also did work for King Edward's Hospital Fund, the Hospital Sunday Fund, the Hospital Saturday Fund, and the Red Cross.

Whatever Fripp took up, he strove desperately hard at it; therefore, as he had many interests outside surgery, he was always working at high pressure. The chief of these was assisting invalids, especially those who were just not the cases for hospitals. He had been for many years a strenuous helper of the Invalid Children's Aid Association, always thinking of new plans for raising money and of new classes of invalids to benefit from it. Two years ago he broadcast for it and by this means got over £1,000;

altogether he has raised £10,000 for it, besides inciting innumerable people to become subscribers. It is owing to his enterprise that the home at West Wickham, with eighty beds for children suffering from rheumatic heart disease, was opened in 1928. He founded many branches in London, and was chairman of the Hackney branch, the meetings of which he always held at his house. It is largely due to him that the association has now on its books 52,000 invalid children, all being aided directly by it. There are, of course, many other doctors helping, but this association was especially dear to Fripp's heart, and no trouble was too great for him to take over any case that chanced to come to him personally.

When a student Fripp was an ardent first-nighter, and he remained so till the end; consequently, he came to be an excellent critic and to know almost everyone in the theatrical profession. Many of the leading actors and actresses were his personal friends, and many, from the most celebrated to the humblest, are beholden to him for kindnesses that only a member of our profession can bestow. Few people have had more friends than he. This was entirely due to his honesty, his good nature, his cheerfulness, and his kindliness, which led to his unselfishly putting himself to no end of trouble for anyone in distress. To give only one example of his making friends: we have seen he was a cricketer; within a few weeks of the arrival of an Australian team Fripp knew the members personally. The medical profession owes a great deal to him, for he showed the large world outside it that its vocation is to relieve suffering unostentatiously among rich and poor alike, not letting the right hand know what the left hand doeth.

He always loved Lulworth Cove; for many years he had had a house there, where he worked hard in his garden. The house needed extensive repairs, so he built himself another, moving into it a few months ago, and there he died just before midnight on February 25th. His wife, the daughter of the late Thomas Haywood of Reigate, his two sons, and his three daughters survive him. His eldest son is registrar in the orthopaedic department of Guy's Hospital.

[The portrait printed on the previous page is reproduced from a photograph by Arbuthnot.]

JOHN EVANS, D.S.O., M.D.,

Regional Medical Officer for North Wales.

WE regret to report the death, on February 15th, of Dr. John Evans of Carnarvon, after a distinguished career. He was born in March, 1869, and received his medical education at Liverpool and University College, London. In 1892 he graduated M.B.Lond., and obtained the diplomas M.R.C.S., L.R.C.P.; he proceeded M.D. in the following year. He held appointments as house-physician, registrar, and medical tutor at the Royal Infirmary, Liverpool, and then went to Carnarvon, where he conducted a large practice until his retirement from it in 1920, on being appointed regional medical officer for North Wales. He was a member of the British Medical Association, and served as honorary secretary of the North Carnarvonshire and Anglesey Division from 1906 to 1913; he was also an honorary life member of the Order of St. John of Jerusalem.

Colonel R. H. MILLS-ROBERTS, late president of the North Wales Branch of the British Medical Association, writes:

I first met John Evans in Carnarvon, not long before the South African war. He had, after a brilliant career at the Liverpool Royal Infirmary, joined the late Dr. Robert Parry in partnership; later on he practised alone in the same town. In 1900 John Evans took a combatant commission in the old 3rd V.B. Royal Welch Fusiliers—afterwards converted into the 6th Battalion Royal Welch Fusiliers in the Territorial Army—and became a subaltern in the Carnarvon (H.Q.) Company. He was afterwards promoted captain, and retained command of the company until the great war. He was an excellent Territorial officer, and knew all there was to know in connexion with the work; the papers and appreciations that he wrote after a staff ride or field exercise were masterpieces, and were sometimes sent to the War Office. He frequently acted as adjutant to the battalion. He was one of the original members of the Carnarvonshire Territorial Association, and a regular and valuable attendant at the meetings. He was also a keen Freemason and a local magistrate. In 1914 John Evans did an enormous amount of work in preparing the 6th Battalion Royal Welch Fusiliers for oversea service. He was a man of boundless energy and courage. It was not generally known that he was blind in one eye, but despite this fact he immediately signed on for oversea service as a combatant officer in charge of a company, although in those days a Territorial's obligation did not involve foreign service. When the War Office later requested doctors holding combatant commissions to transfer to the R.A.M.C. Captain Evans complied, and was appointed, with the rank of major, to one of the field ambulances in the Welch Territorial (53rd) Division. He was promoted later on to the command of the unit, with the rank of lieutenant-colonel. He was at the Suvla Bay landing, and afterwards served with the Egypt Expeditionary Force until the end of the war, being awarded a well-merited D.S.O. in 1919. After the war he returned to his practice in Carnarvon, and for some time acted as chairman of pensions boards at Bangor. He was also visiting physician to the Pensions Hospital in that city until it was closed. He was appointed regional medical officer under the Ministry of Health for the North Wales district in 1920. The North Wales doctors were satisfied because they realized that the appointment had been given to a man who not only knew his work, but would also do it, and for whose professional opinion they had the highest esteem. They also realized that they would deal with a man who would always play the game with all concerned. His integrity was above suspicion, and his cheery presence will be greatly missed. He was a great conversationalist and raconteur, with a scintillating brain. As a public servant he will be difficult to replace.

Professor JOHN HAY (Liverpool) writes:

My acquaintanceship with Dr. John Evans dates back to the time when he was medical tutor at the Royal Infirmary, and I was one of his students. I can clearly remember his vivid personality and his enthusiasm. He was a splendid teacher and a most genial and kindly man, always eager to help any students with whom he came into contact. It was a great loss to the School of Medicine and to the Royal Infirmary when he left Liverpool to return to Wales. As regional medical officer for North Wales he found full scope for his ability and personality. Every medical man in his region felt he had a friend in John Evans, and his tact and cheerfulness smoothed out the constantly recurring difficulties which were the inevitable accompaniment to his position.

Dr. D. LLEWELYN WILLIAMS, Divisional Medical Officer (Wales), writes:

The late Dr. John Evans was one of the first batch of regional medical officers to be appointed under the Ministry of Health. He immediately proved himself to be a capable administrator and a sound clinician. The insurance practitioners of North Wales soon found that in Dr. Evans they had a physician of the rank of a consultant, upon whose opinion they could always rely; though a strict disciplinarian, he proved himself to be a counsellor and friend to all insurance practitioners, and, in time, they learnt to look forward with pleasure to his visits. His reports always impressed me as being the work of a man of ability and excellent judgement, and displayed remarkable thoroughness. He was very popular among his medical colleagues, both on the staff of the Ministry in Whitehall and of the Welsh Board of Health. He was a loyal friend and colleague, and will be greatly missed by those who worked with him. His passing away at a comparatively early age is a distinct loss to North Wales and the department which he served so loyally.

THE LATE DR. JAMIESON B. HURRY.

DR. F. J. ALLEN (Cambridge) writes: Dr. Hurry was peculiarly generous in his public gifts. He seemed to realize that it is a duty of those possessing wealth to spend much of it for the benefit of the public rather than for private luxury. In addition to his munificent gifts to the town of Reading, he endowed "The Michael Foster Studentship in Physiology" at Cambridge. He founded this in 1912, with an endowment of £50 a year, the studentship to be awarded in alternate years with a stipend of £100. In 1919 he increased the endowment to £100 a year, and provided for the re-election of the student for a second year in suitable cases, or for the election of another student without any interval.

DR. THOMAS M. CARTER, who died suddenly on February 21st, at the age of 61, studied medicine at the Bristol General Hospital, where he won the gold medal in 1891. In that year he obtained the diplomas M.R.C.S., L.R.C.P., and graduated M.D. in 1893. He practised in Bristol till the outbreak of war, when he was senior major of the 6th Battalion Gloucestershire Regiment. In 1916 he received a commission in the R.A.M.C., and served in Egypt and in the Mediterranean. Proceeding to France, he was appointed to command No. 3 Convalescent Depot at Boulogne, and was awarded the O.B.E. After the war he returned to Bristol, and became a whole-time officer in the National Medical Service. Dr. Carter took an active part in community life. He was a city councillor for six years, honorary secretary of the Bristol branch of the Bristol and Gloucester Archaeological Society, chairman of the Old Bristolians Club, and a past-president of the Bristol Masonic Society at the time of his death. He was a member of the British Medical Association. He leaves a widow, a son, and three daughters.

We regret to announce the death of Dr. W. MCDONOGH ELLIS, which took place in a London nursing home on January 29th, after a short illness. Qualifying M.R.C.S., L.R.C.P. in 1886, Dr. [illegible] M.D.Brux., with honours, in 1888, [illegible] appointments as clinical assistant at [illegible] for Sick Children, Great Ormond Street, and at Moorfields Eye Hospital, and as house-surgeon at University College Hospital. About twenty years ago he took up practice at Woldingham, remaining there till the time of his death. Among his contributions to the medical journals was a report of a case of sudden death during labour (*Lancet*, 1888), and of a case of acute goitre occurring during the puerperal period (*British Medical Journal*, 1890). Dr. Ellis's interests were not solely confined to his practice, and he devoted a great part of his time to the service of the public of the district in which he lived, holding positions on many committees and boards. He was also particularly interested in the work of the British Medical Association, at the time of his death being one of the deputy representatives of the Reigate Division. A patient writes: "Dr. William McDonogh Ellis will be sorely missed amongst his many patients and large circle of friends. The heaviness of mourning is upon our little community; there is scarcely a household but feels stricken; not one of us but sorrows that in this life we shall see his face no more. 'The beloved physician,' a phrase tender in its age-long association, is the one that comes to us, unsought, as we think of him."

We regret to announce the death of Mr. ARCHIBALD R. FEE, B.A., Ph.D., on February 23rd, of septicaemia and broncho-pneumonia following a simple dental operation about a week previously. He was a keen and devoted investigator in experimental physiology, in which subject he was carrying out researches at University College, London, with the aid of a Beit Memorial Fellowship for Medical Research. Only 24 years old at the time of his death, he had already made considerable contributions to the physiology of the kidney. Some of these papers will appear posthumously. His greatest ambition and firm determination was to qualify in medicine, and he had already begun some preliminary studies directed to that end. His loss creates a great gap among his many friends, as among the ranks of those devoted to scientific research. Dr. Fee's home was in British Columbia, which he left with a university degree before he was 20 years old.

By the death, on February 16th, of Dr. T. MCFETRIDGE of Edlington, near Doncaster, at the early age of 45, the West Riding has lost one of its most popular colliery practitioners. Although in failing health for two years, he remained at work until three weeks before his death, which occurred unexpectedly, when he was believed to be on the road to recovery. Born in co. Antrim, Thomas McFetridge received his medical education at Edinburgh, where he graduated M.B., Ch.B. in 1914. He then joined Drs. Battersby and Willey in practice in Doncaster. In 1916 and 1917 he held a commission in the R.A.M.C., and served in East Africa, after which he returned to Doncaster. He took special interest in ambulance work, and in 1921 was made an honorary member of the Order of St. John. During his student days he had been very keen on outdoor sports, particularly hockey, and he was an Edinburgh "blue." He was a regular playing member of the Doncaster hockey team until his health broke down. Dr. McFetridge was a member of the British Medical Association. He leaves a widow and one son. A colleague writes: Fifteen years' hard work in the colliery village of Edlington had endeared him to all his patients, and successors will find it hard to fill his place. The quietest and most unassuming of men, he had a kind word for each child and a pat for every dog.

We regret to announce the sudden death, on February 17th, at the age of 66, of Geheimer Sanitatsrat Professor Dr. JULIUS SCHWALBE, editor of the *Deutsche medizinische Wochenschrift* since 1894. Professor Schwalbe was also co-editor with the late Professor Ebstein of a handbook of practical medicine in five volumes, and works on therapeutic technique, diseases of old age, and a series on diagnostic and therapeutic errors and their prevention. On many occasions the Medical Secretary's department of the British Medical Association has been indebted to him and his staff for help in connexion with various matters raised by members.

The following well-known foreign medical men have recently died: Dr. VERDUN, professor at the faculty of medicine and pharmacy of Lille; Dr. CARL AUGUST HAMANN, professor of applied anatomy and clinical surgery at the Western Reserve University School of Medicine, Cleveland, since 1911, aged 61; Dr. CLARENCE FLOYD HAVILAND, clinical professor of psychiatry, Columbia University College of Physicians and Surgeons, New York, since 1927, aged 54, of influenzal pneumonia; and Professor THEODOR SOMMERFELD, an authority on industrial hygiene and author of numerous publications on tuberculosis, aged 69.

Universities and Colleges.

UNIVERSITY OF LONDON.

DR. FRANCIS DAVIES has been appointed, as from August 1st, 1930, to the University readership in anatomy, tenable at King's College.

The Geoffrey E. Duveen travelling studentship in oto-rhino-laryngology, of the value of £450, has been awarded for 1930 to Dr. C. S. Hallpike.

Professor L. T. Hogben has been appointed, as from August 1st, 1930, to the University Chair of Social Biology at the London School of Economics. Professor William Wright has been appointed a governor of the East London College.

The title of Honorary Fellow of University College has been conferred on Mr. Henry Tonks, F.R.C.S., Slade Professor of Fine Art in the University of London since 1917. The title of Fellow of University College, London, has been conferred on Mr. Gwynne Williams, surgeon to University College Hospital and vice-dean of University College Hospital Medical School, and on Mr. Harold Muir Evans, surgeon to the Lowestoft Hospital.

In the annual record of the work of University College, London, for the year ending February, 1930, which has just been issued, it is announced that the fund inaugurated in connexion with the celebration of the centenary has reached £223,880. A bequest of £12,000 from the late Lady Durning Lawrence is to be applied

to the electrical equipment of the department of chemistry. The department of psychology has been provided with better accommodation, and the reorganized department of municipal engineering and hygiene with an adequate laboratory.

At the January matriculation examination 176 candidates were successful in the first division and 584 in the second division, while 58 took the supplementary certificate in Latin.

UNIVERSITY COLLEGE.

Two lectures, illustrated by lantern slides, on the history of our knowledge of the mechanism of heredity, will be given by Dr. Charles Singer at University College Hospital Medical School, W.C.1, on March 10th and 24th at 4.15 p.m. The lectures are open to all medical students of the University of London.

UNIVERSITY OF MANCHESTER.

PROFESSOR F. E. TYLECOTE, M.D., D.P.H., F.R.C.P.Lond., has been elected chairman of convocation for the ensuing year.

UNIVERSITY OF ABERDEEN.

THE Senate of the University of Aberdeen has decided to confer the honorary degree of LL.D. on, among others, Emeritus Professor Ashley W. Mackintosh, M.D., honorary physician to H.M. Household in Scotland, and consulting physician to the Royal Infirmary, Aberdeen.

The Services.

HONORARY SURGEON TO THE KING.

COLONEL C. L. ISAAC, T.D., Assistant Director of Medical Services, 53rd (Welsh) Division, Territorial Army, has been appointed Honorary Surgeon to the King.

DEATHS IN THE SERVICES.

Lieut.-Colonel Gilbert Saunders Griffiths, Bengal Medical Service (ret.), died at Gibraltar, aged 75, on January 1st, at the residence of his son, Dr. G. H. C. St. G. Griffiths, Colonial Medical Service. He was born on May 3rd, 1854, the son of Thomas Griffiths of Bideford, was educated at the Middlesex Hospital, and took the M.R.C.S. and L.S.A. in 1876. Entering the I.M.S. on September 30th, 1876, he became surgeon lieutenant-colonel after twenty years' service, was placed on the selected list on October 1st, 1902, and retired, with an extra compensation pension, on June 1st, 1904. His whole service was spent in military employ, during which he saw a good deal of active service. He served in the Afghan war of 1878-80, taking part in the Arambi Karej expedition, and the action at Bhagas, and received the medal with a clasp; in the Zhob Valley campaign, on the North-West frontier, in 1884; and in the Sikkim campaign, on the North-East frontier, in 1888, receiving the frontier medal with a clasp. After his retirement he lived for some time at Clifton, but since the war had resided chiefly in Italy and at Gibraltar. In 1887 he married Katherine Celestine, daughter of Henry Colling of Okehampton, Devon, and leaves two sons, one of whom served as surgeon lieutenant R.N. with the Grand Fleet in the war, and is now in the Colonial Service; the other served in France, Egypt, and Palestine as a captain in the R.A.F. He had three brothers in the medical profession: Lieut.-Colonel W. E. Griffiths, I.M.S., Lieut.-Colonel A. Griffiths, R.A.M.C., and Dr. E. Griffiths of Blainey, New South Wales.

Lieut.-Colonel William Coates, Bengal Medical Service (ret.), died at Hove on February 13th, aged 78. He was born on January 20th, 1852, the son of the late Dr. Coates, of Dohanaughta, Galway, and graduated as M.D. and M.Ch. in the Queen's University, Ireland, in 1876. Entering the I.M.S. as surgeon on March 31st, 1877, he became surgeon lieutenant-colonel after twenty years' service, was placed on the selected list for promotion on July 6th, 1903, and retired on July 4th, 1907. Most of his service was passed in civil employ in the Punjab, where for several years he was civil surgeon of Peshawar, and later, for many years before his retirement, of Lahore. He served in the Afghan war of 1878-80, when he took part in the action at Ali Musjid and Kharasiah, in the operations in and round Kabul, and in the famous march under General, afterwards Lord, Roberts, from Kabul to Kandahar, and the battle of Kandahar, which relieved the British garrison besieged in Kandahar, finally settled Ayub Khan, one of the claimants to the Afghan throne, and put an end to the war. He was mentioned in dispatches in G.A.O. No. 137 of 1880, and received the medal with four clasps, and the Kabul-Kandahar bronze star. He also served in the Mahsud Waziri campaign of 1881. After retirement, he rejoined for service in the war of 1914-18, and served as registrar of the York Place Indian Hospital at Brighton in 1914-15, from the opening to the closing of the hospital. He was given a Good Service pension on August 8th, 1927.

Medical News.

THE third Sir Charles Hastings lecture, on Health and the Empire, will be given in the Great Hall of the British Medical Association House, Tavistock Square, W.C.1, on [illegible] March 12th, at 8 p.m., by Sir Andrew [illegible], M.D., director of the London School of Hygiene and Tropical Medicine. The chair will be taken by Lord Riddell, *president of the Royal Free Hospital*. These lectures were inaugurated by the British Medical Association for the purpose of offering to the public information by the highest authorities on matters of general health interest. Admission to the lecture is free by tickets obtainable from the Financial Secretary, B.M.A. House, Tavistock Square, W.C.1. Seats not occupied by ticket holders by 7.50 p.m. will be available for other members of the public.

PROFESSOR E. W. HEY GROVES of the University of Bristol will deliver the Harveian Lecture before the Harveian Society of London on Thursday, March 13th, at 8.30 p.m., at 11, Chandos Street, Cavendish Square, W., and not at Paddington Town Hall as previously stated. His subject is: Should medicine be a mendicant? Visitors will be welcome.

A COURSE of lectures on midwifery will be given at the City of London Maternity Hospital, City Road, E.C.1, on Tuesdays at 5 p.m., from March 25th to June 10th. Particulars will be given in our diary of post-graduate lectures published weekly in the *Supplement*.

THE annual dinner of the Cambridge Graduates' Medical Club will be held at the May Fair Hotel, Berkeley Street, W., on Thursday, March 27th, at 7.45 p.m., with Dr. H. Morley Fletcher, treasurer of the club, in the chair. The annual meeting will precede the dinner.

THE annual general meeting of the Biochemical Society will be held in the department of physiology and biochemistry, University College, Gower Street, W.C., on Friday, March 14th, at 3 p.m. The subjects on which communications will be made include comparative rates of absorption of certain sugars from the human intestine, rate of liberation of arginine in the tryptic digestion of proteins, fermentation by yeast preparations, micro-determinations of hydroxyl groups, alcohol isolated from the urine of pregnancy, an improved method for the preparation of oestrin and the isolation of active crystalline material from urine, observations on the relation of carotene to vitamin A, oxidation-reduction potentials of cultures of haemolytic streptococci, and the phosphorus distribution in blood during hypervitaminosis.

H.R.H. PRINCE GEORGE, President of University College Hospital, will open the new preliminary training school for nurses, presented by the Rockefeller Foundation, on Wednesday, March 19th, at 3.30 p.m. The ceremony will take place in the library of the medical school.

A JOINT meeting of the Section of Psychiatry of the Royal Society of Medicine with the British Psychological Society, at 1, Wimpole Street, W., on Tuesday next, March 11th, at 8 p.m., will discuss "The role of psychotherapy in the treatment of the psychoses." The speakers will be Dr. H. Devine, Dr. Edward Glover, Dr. R. D. Gillespie, and Dr. H. Yellowlees.

THE Fellowship of Medicine announces that Mr. W. *Girling* Ball will lecture on the differential diagnosis and treatment of infections of the urinary tract at the Medical Society's lecture room, 11, Chandos Street, Cavendish Square, on Tuesday, March 11th, at 4 p.m. Mr. J. Bright Banister will give a demonstration of gynaecological operations at the Chelsea Hospital for Women, Arthur Street, on Monday, March 10th, at 2 p.m., and Dr. J. E. M. Wigley will give a dermatological demonstration at St. John's Hospital, Leicester Square, on Tuesday, March 11th, at 6 p.m. This lecture and the demonstrations are free to medical practitioners. On March 10th an all-day course will start at the Brompton Hospital for Consumption and Diseases of the Chest, comprising lectures, demonstrations, and ward rounds, and lasting for one week. From March 10th to 22nd there will be a course at the Royal National Orthopaedic Hospital, beginning with operations each morning at 9 or 10 o'clock, and followed at 11.30 by a lecture-demonstration; in the afternoon there will be clinics in the out-patient department. From March 17th to April 12th a course in neurology will be held at the West End Hospital for Nervous Diseases at 5 p.m., and during the same period one in venereal diseases at the London Lock Hospital, occupying every afternoon and evening. There will be an all-day course in medicine, surgery, and gynaecology at the Royal Waterloo Hospital from March 24th to April 12th, and an all-day course in gastro-enterology at the Prince of Wales's Hospital, Tottenham, from March 31st to April 5th. Copies of all syllabuses and other information are obtainable from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE fiftieth anniversary of the foundation of the Ophthalmological Society of the United Kingdom will be celebrated by a banquet to be held in the hall of the Fishmongers' Company on Friday, April 4th.

THE seventh of a series of dances in aid of the Royal Medical Benevolent Fund Guild will be organized by the Middlesex Hospital and held on Thursday, March 27th, from 8.30 to 12.30 o'clock, in the Great Hall of the British Medical Association, Tavistock Square, W.C. Tickets (single 6s., double 11s., including light refreshments), may be obtained from Mrs. A. E. Webb-Johnson, 35, Grosvenor Street, W.1. Application for bridge tables should be addressed to Miss Warwick James, 2, Park Crescent, W.1. Tickets, 6s. each; players to provide their own cards and markers.

A POST-GRADUATE course will be held in Vienna from May 26th to June 7th, dealing with tuberculosis and its treatment. In connexion with this course classes will be held at certain institutions in Vienna for dealing with special diseases. Further information can be obtained from the secretary of the International Post-Graduate Courses, Dr. A. Kronfeld, Porzellangasse 22, Vienna IX.

THE twelfth salon des médecins for the exhibition of pictures, sculpture, engravings, and decorative art by medical practitioners, dentists, veterinary surgeons, pharmacists, and their families, will be held at 117, Boulevard St. Germain, Paris, from June 15th to the 24th. Further information can be obtained from the organizer, Dr. Paul Rabier, 84, Rue Lecourbe, Paris XV.

UNDER an agreement with University College, London, Messrs. H. K. Lewis and Co., Ltd., the well-known medical booksellers and publishers, are erecting a new building on the site of 134, Gower Street, of which they will occupy the basement and the ground and first floors, the three upper floors being occupied by the College with a separate entrance and stairway from Gower Street. When this building is completed it has been arranged that the company shall use the whole of the building while their old premises of 136, Gower Street, and 24, Gower Place, are being pulled down. On this site a new building will be erected by the company in general conformity with the new premises at No. 134 and the rest of the College buildings in Gower Street. Some sacrifice of space and convenience on the company's own site at the corner has been made to architectural necessities, in order to secure a satisfactorily artistic effect in carrying out the general design, but the completed building, with the portions to be occupied by the company in what was No. 134, will give much needed increased space. The scheme originated shortly after the late Professor Simpson's retirement from the chair of architecture at University College, and he prepared the first plans. His son, Mr. J. R. Moore Simpson, A.R.I.B.A., has designed the building now to be erected, and the work is in the hands of Messrs. Ford and Walton, who completed the building of the British Medical Association's House. While Messrs. Lewis are in occupation of No. 134 there will be many temporary difficulties to contend with, but plans are being carefully considered to ensure that these shall be overcome.

AT the annual meeting of the Glasgow Eye Infirmary, held on February 24th, it was stated that contributions from employed persons amounted to nearly-half of the infirmary's total revenue.

THE twentieth annual professional nursing, midwifery, and public health exhibition and conference has been held this week at the new Horticultural Hall, Westminster. Lectures were given each day, and various cinematograph films, including the Harvey film, were shown.

THE register of members (July, 1920, to November, 1929) of the Chartered Society of Massage and Medical Gymnastics contains particulars of the purposes of the society, conditions of registration, and of the admission of members to the roll of biophysical assistants. A place index is appended, and the present issue gives additional professional qualifications. The price of the register is 4s. It should be noted that the address of the society after March, 1930, will be Tavistock House (North), Tavistock Square, W.C.1.

THE problem of landing from fishing vessels, and under the general conditions obtaining on them, an increased proportion of fish in first-class condition has for some years engaged the attention of the Food Investigation Board, and under the supervision of the Food Transport and Distribution Committee of the Board an inquiry was carried out in 1927 and 1928 on the causes of deterioration of commercially handled fish and of the methods by which the rate of such deterioration might be slowed down. In a special report (No. 37, H.M. Stationery Office, price 1s. 6d. net), entitled "The Handling and Stowage of White Fish at Sea," which has been issued from the Department of Scientific and Industrial Research, Messrs. Adrian Lumley, J. J. Piqué, and George A. Reay describe the technique of this inquiry, which, they are able to show, has produced results capable of immediate commercial application. The investigators reach the general conclusions that the deterioration of fresh fish while on board the trawler is mainly due to bacteria present when the fish is caught and acquired during the process of gutting, handling, and stowage; that ice acts as a preservative by slowing the activities of bacteria, but does not arrest their growth; and that by the use of cleanlier and more careful methods than those at present employed the deterioration of the fish in ice will proceed at a still slower rate, whereby the duration of freshness will be extended from 6–7 to 10–12 days, the fish will be consistently fresher, age for age, and a larger proportion of the total catch will be landed fresh.

THE *Journal de Médecine et de Chirurgie Pratiques*, founded by Lucas Championnière, and continued first by his sons Just and Paul and later by his grandsons Henri-Paul and Just-Lucas Championnière, will celebrate its centenary this year. The present editors are Maurice Vigneric, son-in-law of Lucas Championnière, and René Mignot.

DR. THORVALD MADSEN of Copenhagen, president of the Health Committee of the League of Nations, has been made a doctor *honoris causa* of Frankfort University, and Dr. Egaz Moniz, professor at the medical faculty of Lisbon, has received a similar distinction from the Lyons medical faculty.

PROFESSOR RUDOLF KRAUS of Vienna, formerly director of the Butantan Serotherapeutic Institute at São Paulo, has been appointed director of the bacteriological institute of Chili; Dr. Karl von Angerer of Munich, professor of hygiene at Erlangen; and Dr. Fritz Paneth of Berlin, professor of chemistry at Königsberg.

IN our issues of May 14th, 28th, and June 4th, 1927, we published a series of articles describing a medical tour of the Czechoslovak spas. Another visit to Czechoslovakia on corresponding lines has been arranged for the coming Easter holidays. The party will leave Liverpool Street Station on the evening of Monday, April 14th, and travel via the Hook of Holland and Germany. The places to be visited include Teplice-Sanov, Carlsbad, Jáchymov, Franzensbad, Marienbad, Prague, Podebrady, Luhacovice, Trencin-Teplice, Pistany; three days will be spent in the Tatra Mountains, and a night at Dresden on the way home; and the party is due back in London on the morning of Monday, May 5th. As on the last occasion, special facilities and courtesies will be extended to the visitors by the Czechoslovak Ministry of Health. Readers who wish for particulars should communicate with Mr. Henry Baerlein, Bath Club, 34, Dover Street, London, W.1.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the *British Medical Journal* are *MUSEUM 9561, 9562, 9563, and 9564* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR OF THE *BRITISH MEDICAL JOURNAL*, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocrra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62559 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

TINNITUS AURIUM.

DR. W. A. M. SWAN (London, N.W.1) would be grateful for suggestions for treatment of very troublesome tinnitus aurium in a patient aged about 65. She refuses electrical treatment, diathermy, etc., and most of the usual nerve sedatives have been tried without effect.

Effects of the Prolonged Administration of Liquid Paraffin.

"P. C. F." asks whether the continued administration of liquid paraffin in large doses over a period of years to young children for the treatment of chronic constipation is likely to inhibit growth. He suggests the likelihood that a bowel perpetually coated with a fine film of paraffin may be hampered in its work of assimilation.

Hot Feet.

"W. M." writes: I should be grateful if anyone could suggest some remedy for hot feet. An old lady, who all her life suffered from cold feet, now has the opposite, necessitating getting out of bed at night and walking about to cool them. Various things have been tried, but with little effect.

Rheumatic Manifestations after Dick Immunization.

Dr. C. Fraser Brockington (Bromsgrove) asks whether there is any record of the occurrence of rheumatic symptoms after the injection of scarlet fever toxin. A man, aged 26, who was very strongly Dick-positive, received his first inoculation of 500 skin doses on May 21st, 1929; a moderate local reaction followed, but no general reaction. One week later he had a second inoculation of 1,000 skin doses, which was followed by a rise of temperature to 100°, severe local and general reactions, intensive headache, muscular aches and pains, and a furred tongue. On June 1st, eleven days after the first injection, the first interphalangeal joints of the fifth and middle fingers of the left hand were swollen, red, and painful for one day. On June 4th he had a third inoculation of 2,500 skin doses, which gave rise to severe local and general reactions, intense headache, pains and aches, and a temperature of 100°. On June 15th the first interphalangeal joint of the index finger of the right hand became swollen, red, and painful, the condition lasting for one day. On June 18th he had a fourth inoculation of 3,000 skin doses, which caused very little reaction, but thirteen days later there was a temporary swelling of the first interphalangeal joint of the fifth finger of the right hand, lasting twenty-four hours. The Dick reaction was negative on July 3rd, 4th, and 5th, and no further inoculations were given.

Buccal Ulcer.

"W. G." writes: In reply to the inquiry of "R. D." in the *Journal* of February 8th (p. 267) about the treatment of intermittent crops of buccal ulcers, I found far the best treatment was to apply a small pointed piece of copper sulphate as soon as a spot was felt or seen, and repeat for one or two days if necessary. My patient usually noticed that the ulcers were worse when salads, tomatoes, and such-like were eaten.

Broken Sleep.

"E." writes in reply to the inquiry by "D. S." (February 22nd, p. 371): For wakefulness in the early hours of the morning I suggest a cup of hot tea with an unsweetened biscuit. I find this very useful.

Glass Permeable to Ultra-violet Rays.

Mr. G. L. Pilkington, on behalf of the Vita Glass Marketing Board, writes: Dr. Dyson says (February 22nd, p. 372) that even when the sun is shining in winter the minute particles of water in our damp atmosphere effectually cut off all the ultra-violet rays. The National Physical Laboratory has been taking direct photographs during this last winter at Teddington, and in no instance has it found that the spectrum did not extend as far as wave length 3,100 A.U., a point well within the health band of the ultra-violet rays in sunshine. Experiments we have done ourselves in North-country manufacturing towns give similar results, and photographs taken in a room glazed with Vita glass in our works at St. Helens on dull winter days with no direct sunshine show the spectrum ending below 3,100 A.U., whereas in a similar room glazed with ordinary glass the spectrum always ends at 3,200 A.U. The statement that "ultra-violet rays cannot pass through even the very thinnest piece of clothing" is against the weight of evidence, as many materials transmit these rays in a high percentage, notably artificial silk. The question of clothing, however, is not of very great importance, as the work of Eidinow, Colebrook, and Hill has shown that an area of skin represented by face and hands is quite sufficient to give a beneficial result from prolonged insolation. The fact that the face of the average person in this country is much paler in winter than it is in summer shows that the skin is sensitive to the seasonal variations in the intensity of the ultra-violet light.

Income Tax.

Purchase of New Car.

"H. W." explains that A and B are in partnership, each supplying his own car. Depreciation has not been claimed, it being agreed that the cost of renewal should be allowed when incurred. A has recently bought a new car for £400, but wishes to retain the old one (worth about £30) for occasional professional use. If this is done can he claim cost of renewal, and, if not, would it affect the matter if the old car were sold by A to the firm for £30.

*** A cannot claim to deduct the cost of replacing the old car so long as it is retained and is available for use. If he sells it to A and B it is arguable that A could claim cost of renewal, but as the income tax liability has to be computed and assessed on the firm as a distinct entity and not on A and B separately, such a sale would savour of an artificial transaction for tax purposes only, and we think that the authorities would refuse it. A and B would, of course, have the right of appeal to the District Commissioners or to the Special Commissioners, but in view of the above consideration we should not regard the prospects of appeal as very good. This case illustrates the disadvantage of not claiming the annual deduction for depreciation of cars.

LETTERS, NOTES, ETC.

Treatment of Ulcerative Colitis.

Dr. R. Bindon Brew (Penarth) writes: In view of the recent articles in the *Journal* on ulcerative colitis it may be of interest to record the case of a widow, aged 35, who, at the end of April, 1929, suffered from diarrhoea, with blood in the motions. The haemorrhage increased and she was confined to bed about the middle of May. When I saw her on May 22nd the pulse was 120, the temperature 100° F.; there was tenderness and rigidity in both iliac fossae, with signs of perityphlitis and pericolitis. The motions averaged twenty a day; they were offensive, bright red in colour, and contained about half a dozen green sloughs, the size of a shilling, in each motion. No pathogenic organisms or parasites were detected, and there was no serological reaction for typhoid or dysentery bacilli. No improvement followed the administration of tincture of opium, and she was admitted to hospital, which she left a month later without benefit. On July 28th she was still incontinent; the rigidity persisted in both iliac fossae, and the motions were dark brown in colour, containing pus and a material resembling red jelly. Her feet became swollen, and within four or five days dropsy spread to the whole of the body; the heart was dilated, and there was evidence of ascites. I attributed this dropsy to the profound secondary anaemia, since there was no albumin in the urine. Mental symptoms then developed, including forgetfulness and visual hallucinations. She was treated with tincture of digitalis, a bismuth mixture, and tincture of opium. The dropsy cleared up in about three weeks, and on September 5th she was given 25,000 units of antidysenteric serum. Two days later the pus and red jelly disappeared from the stools; she was able to get up on September 10th for a few hours, and rapidly regained health. Menstruation, which had been absent throughout her illness, started again. There has not been any suggestion of relapse.

Artificial Pneumothorax.

"T. G. M." writes: At the meeting of the Medical Society of London on February 10th Mr. Morriston Davies, in his support of the treatment of pulmonary tuberculosis by artificial pneumothorax, states what is, of course, a commonplace when he says: "In pneumothorax the presence of activity in the opposite lung did not necessarily preclude it." Now that may be true as a mere matter of clinical observation, but such a view is almost always associated with an axiom, as it is in this case. "In many cases what was wanted was a partial collapse with immobilization and resting of the lung." The question has been asked why it is that immobilization of the one lung does not produce a flare-up in the partially affected lung. The partly affected lung is called upon to make up for the lack of ventilation in the collapsed lung, and seeing that there is no definite means of determining whether toxicity which may be present may not be due to the smaller lesion, such advocacy is surely contrary to all that is meant by demobilization and rest. The question of lung reserve does not meet the objection, since, except with absolute rest, it is not to be hoped that the reserve may not be fully called upon. The assumption is that the salutary operation depends upon some other principle than their demobilization.

Large Cerebral Haemorrhage with Few Symptoms.

"E. A. C." writes: I was called to see a man whose wife sent an urgent message that he was suffering from a "terrible" headache. I found him [illegible] vomited two or three times, and was very [illegible]s arms about. In reply to my query as to [illegible] was denied. There was no inequality of the pupils, [illegible]e pulse was regular, though rapid. I gave him 1/4 grain morphine with atropine 1/150 grain; a quarter of an hour later he appeared better, though he was unconscious. I was again sent for in less than an hour, and found him dead. At the inquest evidence was given that he had received an injury about six weeks before. First aid was administered at the place where he was working, and he did not think it necessary to consult a doctor. His wife said that after the accident she noticed that his hearing was not so good, and that he complained of pains in his head. On the surface of the left side of the brain I found a track of adhesions about an inch wide, between the dura and brain surface, extending the whole length, and, opening the left side of the brain substance, an extensive haemorrhage, occupying the whole length, was revealed. Since this man was in good health, not suffering from any specific disease, and his brain was otherwise healthy, it is difficult to dissociate the history of this apparent trivial injury, which did not give rise to any serious symptoms six weeks preceding his death. Perhaps some reader could quote a parallel case.

Vacancies.

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 44, 48, 49, 50, and 51 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 45 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 75.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

225. Oedema in Bright's Disease.

H. CHABANIER, C. LOBO-ONELL, M. LEBERT, and E. LÉLU (*Journ. d'Urol.*, December, 1929, p. 598) state that in recent years numerous observations of the syndrome formerly designated "epithelial nephritis or oedematous Bright's disease," but now termed "lipoid nephrosis," have determined the different humoral characteristics of this affection. Attention, however, has been paid rather to the processes of cure and the value of therapeutic measures than to the pathogenic significance of the humoral changes. The authors agree that the pathogenesis is obscure, and report in detail a case which illustrates its complexity. The patient had albuminuria and a marked anasarca, which subsided after an acute attack of diarrhoea. The symptoms returned and the patient entered hospital, from which time the disease could be classified as passing through three phases. During the first, injections of thyroid extract produced no results. During the second, seven intramuscular injections of neptal were given, which resulted in a lessening of the oedema, but had no effect on the humoral changes. In the third phase, thyroid extract was again administered together with ammonium chloride, and, the weight having increased, two intravenous injections of sodium citrate were given. At the end of this phase a second crisis of profuse diarrhoea occurred, which was followed by a progressive return to normal of the humoral characters, and final cure. During treatment a hyper-nitrogenous diet was given. The authors remark that a characteristic of the disease is diminution of the proteins of the plasma; this is caused by a reduction in the serum albumin, the serum globulin remaining normal, or even being raised in some cases. This increase in the globulins cannot be fully explained by the dilution of the blood or by the albuminuria and loss of serum albumin by the kidney. The authors suggest that disturbance of the equilibrium normally existing between the proteins of the plasma may be due to metabolic irregularities, and cite the frequency of lowered basal metabolism in oedematous forms of Bright's disease. Another characteristic is chlorine retention; the authors believe that this change in the renal elimination of chlorine is due to the disequilibrium in the plasma proteins, and is not a primary cause of the disease. Changes also occur in the plasma lipoids. The final disappearance of the oedema in the present case is attributed to the very intense diarrhoea, which apparently drained away the excess of water. With regard to the part played by the treatment and diet in aiding the cure, the authors refer to several cases in which cure has followed similar measures.

226. Imperfect Inoculation against Diphtheria.

P. LEREBOULLET and J. T. GOURLAY (*Paris Méd.*, December 14th, 1929, p. 519) state that although the successful results of active immunization against diphtheria are generally recognized in France, several cases have been recorded, especially at the Société de Pédiatrie, of diphtheria, the diagnosis of which was confirmed bacteriologically, occurring in persons who had received the proper number of injections of anatoxin. Most writers, however, have insisted on the small proportion of such cases, which amounts to some 3 to 5 per cent. of those injected. The present authors maintain that a considerable number, and perhaps the majority, of these apparent failures have not really been properly inoculated. Inquiry in many cases showed that the child had not received the three injections, that a Schick test had been mistaken for an inoculation, or that the child had been registered as inoculated when as a matter of fact he had escaped. In several cases the practitioner had injected antitoxin and not anatoxin, in one instance of this kind owing to illegible writing on the doctor's prescription. The authors maintain that the incidence of diphtheria among those inoculated with anatoxin is very small, if the following cases are not included: (1) those which have been given only one or two injections instead of three; (2) the numerous cases in which there has not been the proper interval of three weeks between the first and second injections, and a fortnight between the second and third; (3) those in which diphtheria developed in less than two months after the last injection (the date of complete immunization after inoculation being variable); and (4) cases in which inoculation was not properly carried out, for reasons already given. Among 17,000 children who had been inoculated with anatoxin at the Hôpital des Enfants Malades, Paris, there were only five in whom the diagnosis was confirmed bacteriologically who developed diphtheria. One was a mild laryngeal case, and four were faucial cases, two of which were cases of Vincent's angina in diphtheria carriers. On the other hand, there were ten mild faucial cases in patients who had had only two injections, and at least fifteen in those who had had only one.

227. Pernicious Anaemia in a Boy.

P. F. ECKMAN and O. W. ROWE (*Minnesota Med.*, December, 1929, p. 788) report the successful treatment of a case of pernicious anaemia in a boy, aged 11, who was almost moribund when first seen. On examination the haemoglobin percentage was found to be 25; the red corpuscles numbered 1,450,000 per c.mm., and the white cells 20,100, 70 per cent. of the latter being polymorphonuclears. Anisocytosis and poikilocytosis were marked. There were numerous macrocytes present, many of which were polychromatophilic or loaded with basophilic granules. The cells were generally well filled with haemoglobin. A few normoblasts and an occasional megaloblast were noted. Many of the polymorphonuclears were rather larger than normal and showed very definite over-segmentation and stranding: some of these nuclei contained as many as eight to ten thinned-out lobules. These cells are regarded by Watkins as diagnostic of pernicious anaemia. Owing to the patient's condition he was given a transfusion of 450 c.cm. of citrated blood on the day of admission; his condition definitely improved, the haemoglobin percentage rising to 42, the red blood cells to 1,808,000, and the white blood cells falling to 12,700. Examination of the vomitus showed no free hydrochloric acid present, and a combined acidity of 26. On the fourth day treatment with liver extract was begun, using four phials (Lilly's 343) daily; a few days later the dosage was increased to six phials, with the addition of a raw liver cocktail once daily. The diet was made as general as possible, and included certain portions of meat, fruit, and cooked vegetables each day. Before any appreciable effect was noted in the blood counts a very obvious change in the patient's general attitude, appearance, and appetite occurred very soon after beginning the administration of liver extract. After three months' treatment his count remained quite normal and he had put on 20 lb. in weight.

228. Treatment of Stokes-Adams Syndrome.

F. W. PRICE and B. S. NISSE (*Amer. Heart Journ.*, December, 1929, p. 197) classify the conditions under which Stokes-Adams attacks may occur as follows: (1) in suddenly developed, transient, complete auriculo-ventricular block; (2) when periods of complete block or increased grade of block occur in a patient the subject of partial heart-block; (3) if the ventricular rate in permanent complete block falls below 30 per minute. Of these three groups the second is the largest; cases corresponding to the first group are rare, while periods of asystole become less frequent when complete block is established. The morbid conditions causing auriculo-ventricular block are overaction of the vagus, diminished irritability of the ventricular myocardium, and gross lesions—sclerotic, gummatous, or inflammatory—involving the junctional tissues. Therapeutic measures in Stokes-Adams syndrome are directed essentially to increasing the ventricular rate, and to the resolution of a junctional lesion if present. Antisyphilitic treatment has at times been successful where gummatous infiltration has been the causative factor. The exhibition of the iodides is considered harmful in cases other than syphilitic, since they depress the myocardial irritability. The administration of thyroid extract has occasionally given good results, while atropine is specially valuable in preventing attacks when these are due to vagal overactivity. Digitalis may increase the excitability and contractility of the heart muscle in complete block, but it is contraindicated in partial block owing to its depressant effect on the conducting system. Adrenaline is the only potent therapeutic agent during an attack, intracardiac injection being usually necessary. For the prevention of attacks, barium chloride by the mouth, half-grain doses twice daily, increasing to one grain thrice daily, is recommended. The authors describe two cases: in one of them exceptionally severe Stokes-Adams attacks were stopped by the administration of barium chloride when other remedies had failed; in the other, complete block complicated by Stokes-Adams syndrome was relieved by barium chloride and adrenaline, the former drug alone being ineffective.

229. Cerebro-spinal Meningitis simulating Acute Poliomyelitis.

J. MAGE and L. VAN BOGAERT (*Ann. de Méd.*, November, 1929, p. 377), who record a fatal case, emphasize the rarity of the spinal forms of cerebro-spinal meningitis, of which only a few genuine examples have been published. In most cases the condition is a diffuse meningomyelitis with predominance of motor or sensory disturbance according to the extent of the areas invaded. In such cases the disease is manifested by flaccid paralysis similar to that found in acute poliomyelitis. During the first days of the disease the patient notices a feeling of weakness in one or more limbs, which he has difficulty in moving. As a rule the loss of power is accompanied, or even preceded, by more or less violent pain in the limb affected and corresponding part of the trunk, whether it be the scapular or lumbar region. In some cases these symptoms do not appear until after the meningeal phenomena have subsided, while in others the symptoms of meningitis and poliomyelitis occur simultaneously. In any case the paralysis is flaccid, and is accompanied by loss of the reflexes and sometimes by sphincter changes. The paralysis becomes more definite during the following days, and may even invade the neighbouring groups of muscles, while the pain and sphincter troubles disappear. Muscular atrophy is then noted with, sometimes, changes in the electrical reaction, and even reaction of degeneration. Subsequently a partial regression of the paralysis and atrophy follow, only a few muscular groups being affected. The present patient was a man, aged 20, in whom the disease assumed three characteristic stages: (1) a stage of invasion resembling poliomyelitis, though the nature of the disease was soon discovered by the presence of meningococci in the spinal fluid; (2) a stage of attenuation of the symptoms, although the patient proved refractory to polyvalent anti-meningococcal serum, of which more than 500 c.cm. were injected; and (3) a terminal stage of *Staphylococcus aureus* meningitis. At the necropsy, in addition to the lesions of acute meningitis, the most important changes found consisted in a process of anterior poliomyelitis, though it did not present the appearance of the massive and acute degeneration found in Heine-Medin's disease.

Surgery.

230. Carcinoid of the Vermiform Appendix.

A. POP (*Zentralbl. f. Chir.*, December 14th, 1929, p. 3168), who records an illustrative case, states that among the benign tumours of the appendix a considerable number of cases of carcinoid have been recorded. The nature of these tumours has led to considerable discussion without any decision having yet been reached. Of 139 cases of carcinoid of the appendix collected by Simon, 77 per cent. were at the distal end (especially the tip), 14 per cent. in the middle third, and only 7 per cent. at the proximal end; in 2 per cent. the whole organ was affected. In the majority of cases the tumours were found accidentally at the necropsy. In 65 per cent. of the cases of carcinoid of the appendix females were affected, only 35 per cent. of the patients being males. The condition is liable to occur at any age, especially in the second and third decennium, which corresponds to the usual period for inflammatory processes in the appendix. Pop's experience does not agree with that of Millner, who asserts that carcinoid constitutes 1 per cent. of all cases of appendicitis, as among nearly 3,000 cases of appendicitis operated on in Professor Jacobovici's clinic at Cluj, where Pop is working, the present case was the only example of carcinoid. The patient was a girl, aged 16, admitted to hospital with symptoms of acute appendicitis. Appendicectomy was performed, and the appendix was found to present a carcinoid at the proximal end and acute appendicitis at the distal end. Recovery was uneventful.

231. Fractures of the Carpus.

IN order to ascertain the reasons for the persistent distressing pain and limitation of function following carpal damage, H. H. RITTER (*Surg., Gynecol. and Obstet.*, December, 1929, p. 838) has made a study of 25 cases of carpal injury, and reports his conclusions. A brief review of the anatomy of the carpus is given and the mechanism of the injuries is described. When the hand is in dorsal and radial flexion, as it is in falls on the outstretched hand, the scaphoid is in direct contact with the radius and lies between that bone and the os magnum, so that the shock of a blow starting in the hand is carried through the os magnum to the scaphoid and thence to the radius. If the radius does not give way (Colles's fracture), the scaphoid breaks, receiving the full force of the violence with the wedge-shaped os magnum jammed against it; if the force continues the anterior ligament yields, with resulting dislocation of the semilunar bone. If the hand is in dorsal and ulnar flexion the violence is transmitted through the semilunar bone against the anterior ligament, which tears, allowing this bone to escape through a rent in the capsule and become dislocated. The scaphoid is more often damaged than all the other carpal bones, and dislocation of the semilunar bone is frequently associated with a fracture either of the scaphoid or the articular surface of the radius. Much of the disability following carpal injuries is due to damage of the intra-articular soft structures. Osseous union in carpal fractures is exceptional; fibrous union the rule. Signs and symptoms common to all carpal injuries are swelling, limitation of motion, pain aggravated by motion, and acute tenderness over the site of the lesion. Early attempts at closed reduction of scaphoid fractures and semilunar dislocations should be made, and, if these fail, an open operation should be performed immediately. Carpal fractures treated unsuccessfully by immobilization should be operated on within three months lest irreparable arthritic changes take place. These fractures, except fractures of the tubercle of the scaphoid, do not heal readily, and no fracture or dislocation of the carpus exists without an associated chondritis, synovitis, and tenosynovitis. Both wrists should always be x-rayed as an aid to diagnosis, but physical findings should be the guide in judging end-results.

232. Joint Complications of Varicella.

A. MARTIN (*Journ. de Med. de Paris*, November 28th, 1929, p. 1014) remarks that, although varicella is usually a mild disease, cases sometimes occur in which articular, peri-articular, or para-articular complications develop during convalescence, or, more rarely, in the first few days of the disease. Since 1919 Martin has seen three cases of suppurative arthritis of the limbs, four of suppurative myositis, two of suppurative bursitis, and one of suppurative synovitis. The symptoms of suppurative arthritis are typical, and the condition may lead to ankylosis. If an operation is not performed septicaemia develops, and death ensues. The muscles involved in suppurative myositis were the biceps on the fifty-third day, the supinator longus on the twenty-eighth day, and the glutens maximus in two cases on the thirty-fifth and fortieth days respectively. In each case the suppuration appeared in the neighbourhood of the joint. The diagnosis of myositis is difficult; before operation it was impossible to say whether the lesion was in the bone or the joint. In the three cases in which a bacteriological examination was made streptococci were found. In the cases of suppurative bursitis the olecranon bursa was involved in one case and the trochanteric bursa in the other. Recovery followed operation in three weeks and three months respectively. In the case of suppurative bursitis the synovial sheath of the peronei was involved with considerable oedema of the foot and pain in the movements of the tibio-tarsal joint, simulating osteomyelitis of the tarsus or astragalus. The temperature fell again after incision, but the synovial sheath remained thickened for three months and required treatment by ultra-violet rays and heliotherapy.

233. Treatment of Hernia by Subcutaneous Injections.

F. S. JAMESON and J. CANTALA (*Med. Journ. and Record*, January 15th, 1930, p. 87) describe the method of Piña Mestre of treating inguinal hernia by injections, the results of which are said to compare most favourably with those following herniaplasty, recurrence being less frequent than after operation, and the procedure being simple, harmless, and practically painless. As a rule the hernia is eradicated in ten to fifteen days, and it is not necessary for the patient to stop working during this time. The mortality is *nil*, and the only contraindications are haemophilia and irreducibility of the hernia. The aim of this method is to cause in the canal a seroplastic exudation, which results in adhesions; these obliterate the canal. Mestre found that vegetable, stimulating, and astringent solutions were more efficacious and less irritating than metallic ones; accordingly he devised a mixture the active principles of which are alcohol and tannic acid. When making the injections 2 c.cm. of novocain solution are first injected through the external abdominal ring into the inguinal canal or into the neighbourhood of the internal abdominal ring; the needle is left in place, and after a few minutes the contents of one ampoule of the solution of Mestre are injected very slowly. As the needle does not penetrate the columns of the ring the peritoneum is not reached. No general reactions occur; if slight pain is experienced after the first two or three injections, it can be relieved by the application of hot water to the injection site. There are two types of local reaction—aseptic inflammation of the canal and swelling of the cord—but, unless these are severe, the injections need not be postponed and may be continued daily. The authors have employed this method in 64 cases, in which four recurrences followed. Two of the latter were

due to the carelessness of the patients, but were cured by a few additional injections. The poor health of one patient interfered with the formation of adhesions, and in the fourth case a large sliding hernia could not be controlled long enough to permit adhesions to develop. A properly fitting truss must be worn during the treatment. I. MAYER (ibid., p. 91) states that this method results in cure in 92 per cent. of cases, and that, though meant primarily for inguinal hernias, it can also be used in femoral and umbilical hernias. He claims that permanency of result rather than shortness of treatment is to be desired, and does not advocate a rapid course of ten to fifteen days, since firm obliterating adhesions cannot be thus produced. Fifteen cases are reported, in some of which the patients received treatment thirty years ago.

234. Hydronephrosis.

VON LICHTENBERG (*Amer. Journ. of Surg.*, December, 1929, p. 747) describes hydronephrosis as urinary obstruction or clogging resulting from a distinct anatomical alteration or from a neurogenetic disorder of the urinary tract. The pathological changes in the kidney arising from this can be designated as "back-flow kidney," which term includes the various forms of pyelectasis. Hydronephrosis is not a disease of the kidney, but a disorder of the genito-urinary system. The nature of the obstruction may be mechanical, as in cases of strictures or kinks, or be dynamic following disturbances of the innervation. "Urinary constipation" may exist for some time without symptoms, which in congenital cases may not occur until the second or third decade, by which time the disease is too far advanced for conservative surgical intervention. In some cases there are attacks of pain with retention interchanging with free urinary outflow. Treatment must aim at the relief of symptoms and the prevention of further damage to the renal parenchyma. A conservative procedure is indicated in all cases with bilateral "constipation," or where the other kidney is affected. Acute purulent infection of the parenchyma is no contraindication for plastic surgery, and a case of bilateral urinary constipation with a carbuncle of the kidney on one side was cured by means of a uretero-pyeloneostomy. The temporary outflow of the urine from a small nephrotomy combats the infection, protects the anastomosis, and helps healing. A temporary fistula of the kidney in all plastic operations upon the kidney pelvis is given as the reason for the good operative results obtained. In cases of infected back-flow kidneys,

only after thorough investigation

The majority of cases of distal obstruction can be relieved by conservative measures without the removal of the kidney, and uretero-pyeloneostomy proved satisfactory in many cases, while in spastic conditions an operation similar to the pyloroplasty of Heinecke-Mikulicz is recommended. In strictures at the same point surgical dilatation with bougies has been successful. In 80 cases operated on for renal obstruction the kidney was removed 33 times; the remaining 47 cases were treated conservatively, and there were no deaths in either group.

235. Treatment of Varicose Ulcers and Eczema.

U. CAVALLUCCI (*Rif. Med.*, December 21st, 1929, p. 1722) has treated 156 cases of varicose veins of the legs, of which 89 were complicated with eczema and 67 with ulcers, by the injection of phlebosclerosing substances such as sodium salicylate, mercury biniodide, and quinine bichloride. The eczema and ulcers healed more rapidly and more permanently than was the case with the older methods, which did not prevent frequent and rapid recurrences. The author considers sclerosing injections indicated especially for patients with superficial varices, excepting those with obstruction in the deeper venous circulation. They are not suitable for the subjects of claudicatio intermittens, nor in very advanced and cachectic cases, in plethoric persons, or in those affected

of distilled water), injecting 0.5 to 2 c.cm. of the solution; he found that a minimum of three to a maximum of eight injections over a period of ten to twenty days was sufficient to complete the cure.

236. Banti's Disease cured by Splenectomy.

B. DESPLAS, A. CAIN, and E. PEYRE (*Bull. et Mém. Soc. Nat. de Chir.*, December 14th, 1929, p. 1346) report a case of Banti's disease in a man aged 50. The first symptoms were slight—namely, delayed digestion and a feeling of heaviness in the right hypochondrium; they were relieved by treatment, though after three years enlargement of the liver was noticed. Six years after the first indication of any trouble the patient had a severe haemorrhage followed by faintness, and became very weak, although he recovered slowly until the following year, when he was seized with violent colic, which was followed by three further haemorrhages. After a preliminary examination a diagnosis of mitral disease of the heart was made and digitalis was given, but later enlargement of the liver, and the discovery that the spleen was very large, hard, and painless, caused the diagnosis to be altered to splenomegaly with anaemia. The hypertrophy of the liver suggested Banti's disease which had reached the stage of cirrhosis. Two blood transfusions were given before the operation for splenectomy was performed, and one immediately afterwards. On the third day after the operation pneumonia and oedema of the limbs developed, with raised temperature, but these subsided after another blood transfusion and the patient made a complete recovery. The operation was rendered particularly difficult by the obesity of the patient and thoracic respiration, and also by the fact that resection of the lower costal margin was necessary. Two years afterwards the patient was in excellent health; the anaemia had completely disappeared, and no trace of the original symptoms remained.

Therapeutics.

237. Medical Treatment of Gastric Ulcer.

F. W. WHITE (*New England Journ. Med.*, November 28th, 1929, p. 1075) records his observations, which extended over six or eight years, on the medical treatment of fifty cases of gastric ulcer. X-ray screening and skiagrams proved very useful in the diagnosis and in the observation of progress, lesser curvature ulcers being easily seen, in contrast with the greater difficulty experienced in the case of pyloric and duodenal ulcers. Skiagrams of these lesser curvature ulcers were taken at intervals of two or three weeks during the treatment, and showed that the deformity might change and disappear, the edges of the ulcer become flattened, the crater filled, exaggerated peristalsis return to the normal, and pyloric spasm disappear coincidently with the symptomatic improvement. These changes might be very rapid even in large ulcers, which might disappear in from four to six weeks. One patient, aged 70, died of arterio-sclerosis ten years after being successfully treated for ulcer, and at the necropsy the stomach was found to be normal. As regards the differential diagnosis, gastric ulcer has no one characteristic symptom, but when all the symptoms are considered a very accurate conclusion is nearly always possible, especially if the early results of medical treatment are watched during several weeks of intensive study. Gastric ulcer usually shows early and definite signs of improvement, while cancer is unlikely to alter much. White remarks that, in selecting cases, serious complications such as perforation, recurrent haemorrhage, or persistent pyloric obstruction contraindicate medical treatment. This begins with rest in bed for a week or two, and frequent feeding with the modified "Sippy" diet, with the addition of cereal gruels of a low or moderate alkali content. Focal infections are treated, and tobacco is reduced or prohibited. Belladonna or atropine may be given to relieve the pyloric spasm. Treatment is continued during the remission of symptoms, and the patient is warned that supervision will be required for two years. These patients, like diabetics, must be taught to conduct their own later treatment. All the fifty cases recorded were watched for three years or more: 46 per cent. are reported as being well, and 76 per cent. as either well or better, but one was unimproved. Late operations were performed in seven cases. Periodical re-examination for from three to nine years in fifty cases of gastric ulcer revealed only one case of a suspected development of cancer in an inoperable ulcer; this low figure may be due to the fact that, when the size was measurable, the majority of ulcers were found to be of small or medium size.

238. Dextrose in Pneumonia.

W. W. G. MACLACHLAN, G. J. KASTLIN, and R. LYNCH (*Amer. Journ. Med. Sci.*, January, 1930, p. 93) present some clinical observations, made during the past four years, on the use of dextrose in pneumonia, a treatment which they believe to be of great value, though of definite limitations. They consider that the best way of giving dextrose in pneumonia is as follows. From 400 to 600 grams are given daily by the mouth in the form of dextrose lemonade (200 grams of dextrose dissolved in 1 litre of water, to which the juice of two or three lemons is added). The litre thus contains 800 calories, and the patient should take two to three litres each twenty-four hours. When it is impossible to give dextrose by the mouth in sufficient amount, or when the case appears to be of a toxic nature, a 25 per cent. solution of dextrose is injected intravenously four to six times every twenty-four hours. The quantity injected never exceeds 200 c.cm. at one time, and it must be introduced slowly, at least half an hour being allowed for the procedure. The nutritional value would appear to be the most important factor in this therapy, but

the clinical signs of *improved circulation* after the intravenous injections may, the authors think, indicate a direct action on the heart muscle. This method is a physiological one, and even when an effective polyvalent serum is employed it may still be of value as an auxiliary measure. The authors state that in a first series of 160 cases, dextrose was given only in small amounts intravenously, and only to the patients with toxic conditions; this accounts for the marked difference in the results which were obtained in a second series of 126 cases which occurred in a year when the general mortality was the same. In the second series, which showed a 22 per cent. lower mortality than the first, dextrose was given much earlier in the disease and in larger quantities, both by the mouth and by intravenous injection when necessary. A definite lowering of mortality was noted in all groups which received adequate dextrose treatment.

239. Treatment of Angina Pectoris.

P. MORAWITZ (*Deut. med. Woch.*, November 29th, 1929, p. 1993) regards angina pectoris as a disease dependent on several anatomical and functional conditions, none of which are obligatory. These are arterio-sclerosis, syphilis, narrowing or blocking of the coronary arteries, spastic conditions like claudicatio intermittens, gastro-cardiac complexes, exercise, position of the body; they add abuse of tobacco, but mention that tobacco-angina is rare in the absence of coronary sclerosis. The diagnosis of angina pectoris vera is difficult or impossible, because the physical signs, when present, are not specific, but common to other diseases. Treatment is chiefly general and directed to the *regulation of living*; physical measures such as massage, baths, diathermy, and high frequency currents are commended. During an attack such a medical remedy as nitroglycerin or amyl nitrite may be tried, but these may be without effect or act too slowly. In cases of cardiac insufficiency with coronary sclerosis, Morawitz advises small doses of digitalis combined with chinidin; adaline, bromural, and luminal, given with theobromine, digitalis, iodine, and papaverine, are useful as nerve sedatives. The syphilitic form of the disease is treated with neosalvarsan and other antisyphilitic remedies. Good results have been obtained by the intravenous injection of glucose, 20 c.cm. of a 25 to 50 per cent. solution being injected twice a week. The author cannot recommend the surgical treatment by section of the cervical sympathetic or excision of the thoracic ganglion, considering that so unphysiological an operation, by interfering with the cardiac nervous system, would have a deleterious influence on the heart's action.

240. Treatment of Perforating Plantar Ulcer.

LOUSTE and JUSTER (*Bull. Soc. Française de Derm. et de Syph.*, November, 1929, p. 1080) agree that the treatment of perforating ulcer of the foot is often very disappointing. They report the case of a woman, aged 42, who had been under treatment for five years for tabes dorsalis, and had four series of injections, including novarsenobenzol and grey oil. A perforating ulcer appeared subsequently in the right great toe, and during eight months, in spite of treatment by sulfarsenol and insulin, no improvement resulted. Local ultra-violet irradiations were then tried for one month, and resulted in complete cicatrization.

241. Spleen Therapy in Laryngeal Tuberculosis.

ACCORDING to Dr. F. HUTTER (*Wien. klin. Woch.*, November 28th, 1929, p. 1513) the favourable influence of spleen therapy in tuberculous affections has been confirmed by many workers; raw calf spleen is administered by the mouth or extracts may be injected. The author reports success from spleen therapy in cases of laryngeal tuberculosis, the raw calf spleen being administered as follows. For four weeks he gives daily 50 to 100 grams of spleen, either minced and mixed with soup or lightly grilled, or minced and mixed with condiments, fat, and hard-boiled egg. After two to three weeks of rest the course of treatment is repeated again, and so on. Gastric intolerance of the raw spleen was overcome by the administration of pepsin and hydrochloric acid.

242. Lysed Typhoid Vaccines.

G. CALABRIA (*Rivista Sanitaria Siciliana*, December 1st, 1929, p. 15[illegible]) reviews the favourable results obtained by the administration of lysed typhoid vaccines, which, he claims, reduce the duration of the infection to fifteen to twenty days, and prevents complications and relapse. The dose of the specially prepared vaccine is 0.5 to 1 c.cm. intravenously, or 1 to 3 c.cm. intramuscularly; the dose is gradually increased, injections being given on alternate days until a fall in temperature is obtained. Intramuscular injections, although slower in action, are said to be safer. Resolution may occur in twenty-four hours, and in these cases an intense reaction follows, anaphylactic in type, followed by collapse lasting ten to fifteen minutes. After this the temperature rises to a point higher than that observed before the injection of vaccine, but it begins to fall after ten minutes or so, and the patient recovers consciousness, a normal temperature being regained within twenty-four hours. In the majority of cases, especially with intramuscular injections, the curative process is more gradual and progressive; more injections are necessary, and the reactions are less intense. During the reaction the red and white blood corpuscles are diminished, but in a later stage they increase. The vaccine is said to be contraindicated in renal and heart disease.

Anaesthetics.

243. Death during Induction of Anaesthesia.

R. W. HORNABROOK (*Med. Journ. of Australia*, December 21st, 1929, p. 838) records a case of death occurring in an unmarried woman, aged about 30, during the induction of anaesthesia for examination purposes in a consulting room. The patient had been placed in the lithotomy position upon an ordinary table only two-thirds the length of an operating table, but, having satisfied himself that the pulse was steady, regular, and of good volume, and that she was free from nervousness, and without any abnormality beyond a huskiness of voice, the author departed from his usual routine of never inducing anaesthesia with the patient in an abnormal position and without a preliminary injection of morphine and atropine. Owing to the huskiness of the voice, chloroform was given on a Schimmelbusch mask held well above the face preparatory to continuing with ether. Only a few drops had been used when the patient's heart stopped suddenly, and did not recommence beating, although artificial respiration was continued for two hours, and oxygen was administered through a laryngeal tube. At the necropsy the heart was found to be enlarged, the cavity of the right ventricle being much dilated and distended with dark fluid blood; its wall was thin, and the orifice of the right coronary artery was narrowed. The left lung was adherent to the chest wall, and dilated bronchi at the base contained pus. Death was due to cardiac dilatation and syncope of the right side of the heart. Hornabrook concludes that it was a mistake to induce anaesthesia with the patient in the lithotomy position. He considers that, even when only very small amounts of an anaesthetic are required for any purpose, the patients should be placed upon an operating table, and such a position as the lithotomy one should not be permitted until anaesthesia has been obtained, since the blood pressure is increased by it. He thinks that properly fitted operating theatres in hospitals or nursing homes should be regarded as essential for examinations under anaesthetics.

244. Spinocain in Spinal Anaesthesia.

R. RIVOIRE (*Presse Méd.*, January 25th, 1930, p. 117) discusses the disadvantages and risks attending the use of novocain in spinal anaesthesia; these are essentially due to its diffusion in the cerebro-spinal fluid, the most constant danger being arterial hypotension. The vaso-constrictor nerves leave the cord from the third lumbar to the second dorsal vertebra; the hypotension thus occurs early; it tends to increase as the anaesthetic diffuses, and more nerves are progressively paralysed. Rivoire remarks that a spinal anaesthetic should therefore be non-diffusible, and should remain where it is injected until the anaesthetic effect ends, its action being regular, constant, and prolonged. If of lower density than the cerebro-spinal fluid, it will float up and paralyse the nerve roots with the patient in the Trendelenburg position; if of greater density, the spinal nerves will only be affected when the patient is seated or in Fowler's position. In either case the upper level of the anaesthesia can easily be controlled by the volume injected, and by the degree of inclination of the operating table. The author thinks that the spinocain of G. Pitkin fulfils all these requirements, and he recalls Barker's earlier work on these lines which was reported in the *Journal* in 1907 (vol. i), 1908 (vol. i), and 1912 (vol. i). After much experimenting Pitkin (see *B.M.J.* August 3rd, 1929, p. 184) obtained a stable substance, which he termed amyloprolamin, and, using this as a solvent of novocain, he prepared two solutions of different densities; the one, light, by adding ethyl alcohol, which he named spinocain; the other, heavy, by adding propantriol. Spinocain is of much lower toxicity than novocain, and can therefore be given in much larger doses. It enhances the intensity of the analgesia by increasing its regularity and duration, the latter being from one and a half to two hours. Rivoire considers that there are practically no contraindications to its use, except in supraphrenic operations, when another form of anaesthesia is necessary. To guard against arterial hypotension, ephedrine should also be administered, owing to its vaso-constrictive action, in doses governed by the height

of the anaesthesia desired and the arterial tension of the patient. Post-operative headaches are caused not only by meningeal reaction, but also by hypotension of the cerebro-spinal fluid, due generally to a leaking of the fluid through the tear in the dura mater made by the needle. This can be prevented by using fine needles with short bevels. An hour before the operation an injection of scopolamine and morphine should be given for its sedative effect, and five minutes before the puncture a subcutaneous injection of Pitkin's novocain-ephedrine solution should be administered. The puncture should be made between the twelfth dorsal vertebra and the sacrum, and always in the median line, in order to avoid entering a vein. Owing to its light density spinocain should never be given to a sitting patient, and the patient should not sit up till all the anaesthetic is either fixed or eliminated. Details are given of the doses of spinocain and the heavier solutions, and the positions to be assumed to obtain the various degrees of anaesthesia.

245. Spinal Anaesthesia.

A. E. OLSON (*Minnesota Med.*, January, 1930, p. 4) reports an experience in the use of spinal anaesthesia at St. Luke's Hospital in 168 operations upon the abdomen, pelvis, and lower extremities, most of which were of the major type. He remarks that, while it has a definite field of usefulness, it should be restricted to major operations below the umbilicus in patients whose systolic blood pressure is over 100 and who are physically able to react from the fall in blood pressure. An hour before the operation 5½ grains of allonal are given, and half an hour later 1/4 grain of morphine, with 1/150 grain of atropine, is injected hypodermically. The eyes are covered and the patient is encouraged to breathe deeply to combat nausea; the stomach should be empty in case it may prove necessary to supplement the anaesthesia with a general anaesthetic. A dose of 50 mg. of ephedrine hydrochloride should be given hypodermically with the novocain locally before the puncture; the dosage of novocain is on a basis of 10 mg. to each 10 lb. of body weight. After puncture the head of the operation table is lowered about 15 degrees. During the operation the blood pressure is recorded every five minutes, so that a fall to below 60 may be combated by the injection of 10 minims of adrenaline hydrochloride (1 in 1,000) intramuscularly. In the case of a fall to below 40, intravenous normal saline injections are given with 1 minim of adrenaline in every 100 c.cm. In 25 consecutive cases the only post-operative complications were paralytic ileus in one, pneumonia in one, immediate headache in two, headache after one week's interval in four, and vomiting in six.

246. Novocain Anaesthesia in Gynaecology.

M. ARCIERI (*Il Policlinico*, Sez. Prat., January 13th, 1930, p. 45) states that the local use of novocain, contrary to the practice in general surgery and ophthalmology, has not been much employed in obstetrics and gynaecology. He records eighteen cases in women, aged from 27 to 67, with various gynaecological conditions, such as vaginal prolapse, stenosis of the cervix, cystocele and rectocele, vagino-perineal laceration, and endometritis, in whom infiltration anaesthesia of Frankenhauser's ganglion and internal pudic nerve with a 1 per cent. solution of novocain was sufficient to allow the necessary operations to be performed. The technique was simple and the results were good. The method is said to be specially suitable for private practice.

Obstetrics and Gynaecology.

247. Secondary Anaemia in Pregnancy and the Puerperium.

SINCE the exact nature and course of secondary anaemia affecting the gravid woman is not well understood, P. B. BLAND, L. GOLDSTEIN, and A. FIRST (*Amer. Journ. Med. Sci.*, January, 1930, p. 48) have undertaken a study of 300 cases (200 maternity ward patients and 100 private ones) in the various periods of gestation and in the puerperium, a special effort being made to determine, if possible, the relationship of the existing anaemia to the various associated maternal conditions. Of the hospital patients, one-half exhibited an anaemia during pregnancy, with red cell counts below 3.5 million per c.mm.; of the private cases, 26 per cent. gave counts below the same figure. Thus 42 per cent. of the entire group, regardless of the time of examination, gave counts below 3.5 million cells. It was found that in 82 per cent. of the ward patients and 62 per cent. of the private ones the haemoglobin determinations were 74 per cent. or less. The severity of the anaemia was apparently not affected by parity, age, or blood pressure. There was no conclusive evidence that improvement occurs at term. In 35 patients having two blood determinations in pregnancy, a gain of 200,000 cells or more was found in 14, and a reduction of the same number in 14 others. Several etiological factors, including ill health, foci of infection, toxaemia, and syphilis, were investigated, but the extent of their influence could not be determined. In a large number of the patients a remarkable and rapid recovery occurred within a few days after delivery. It was noted that 34 of 48 women (71 per cent.) having red cell counts below 3.5 million in the last trimester of pregnancy gained over 200,000 cells per c.mm. within ten days after delivery; and of 23 patients definitely anaemic during pregnancy, 20 were fully recovered in six months after delivery. The large percentage of private patients with anaemia indicates that environment alone was not responsible for the condition. Its etiology remains undisclosed; the withdrawal of iron from the maternal corpuscles by the foetus, the existing hydraemia of pregnancy, and a pre-existing chlorosis are all probable factors in its production, and the subject needs further investigation.

248. Disproportion between Foetus and Pelvis.

G. FITZGIBBON (*Journ. Obstet. and Gynaecol. of the British Empire*, Winter, 1929, p. 756) remarks that improved ante-natal supervision, although benefiting the complications of pregnancy, has failed to control those of labour. At present the number of women treated by induction of labour or Caesarean section has increased, but the number of craniotomies, difficult deliveries, and disastrous forceps sequels has not diminished. Inductions and Caesarean section are performed sometimes inadvisedly, and sometimes are not employed when they are really indicated. FitzGibbon states that little more than 1 per cent. of cases of foeto-pelvic disproportion are due to pelvis deformity, and that fewer than 20 per cent. present even mild indications of a rachitic diathesis; the remainder are normal, healthy women in whom the disproportion is only an accident connected with a particular confinement. The increased incidence of foeto-pelvic disproportion during the past two generations may be traced to increased facilities of transport, with intermarriage of differing physical stocks. The findings that may be encountered on vaginal examination during the progress of a trial labour in cases of disproportion are described, together with the therapeutic indications. If early in the first stage the membranes bulge as a large bag into the vagina, and the cervix, although dilated to admit two fingers, is not taken up but projects as a definite vaginal cervix, the prognosis for pelvic delivery is bad and very early rupture of the membranes is to be expected. Caesarean section is indicated at once unless, in a multipara, examination under anaesthesia reveals a compound presentation which was undetected on abdominal palpation. If shortly after rupture of the membranes the cervix is only dilated from three fingers to two-thirds of full, and, instead of crowning, the head has re-formed a vaginal portion, Caesarean section is indicated. The single exception is the multipara in whom non-descent of the head is due to obliquity of the uterus; in such a case, judged by the previous history and by abdominal examination, internal version is justifiable. Vaginal examination less than four hours after rupture of the membranes may show: (1) full dilatation of the cervix, with the head on the perineum; (2) full dilatation, with the head, partially moulded, still engaged in the brim; (3) a cervix which has ceased to dilate and has moved backwards over the presenting part so that the posterior and anterior lips are thinned and elongated respectively; (4) a cervix which has re-formed a vaginal portion with the inner os partially closed down and the outer os relatively more dilated—at the same time the head is free above the brim, often asynclitic, or partially extended. The respective treatments advised in these cases are: (1) low or middle straight forceps application; (2) moderate forceps traction, pubiotomy, or Caesarean section if this is insufficient; (3) forceps traction if the cervix is almost fully dilated and the posterior lip out of reach, otherwise pubiotomy or Caesarean section; (4) Caesarean section. FitzGibbon remarks that in the three groups the forceps is being employed at present with disastrous results and to the exclusion of proper treatment, or the labour is allowed to persist until maternal distress or attrition of the soft parts has occurred.

249. Radium Treatment of Cancer of the Vulva.

I. DE BÜBEN (*Surg., Gynecol. and Obstet.*, January, 1930, p. 110), from ten years' experience with radium and high-voltage therapy in thirty-one cases of cancer of the vulva, considers that radium therapy ranks first among the methods of treatment of the condition. Although permanent cure is exceptional in advanced cases, temporary improvement generally results, the condition being improved and the suffering ameliorated, the life of the patient being prolonged and made tolerable. For local treatment with radium the implantation method gives very satisfactory results in combination with irradiation of the lymph glands with Roentgen

rays. The results compare favourably with those reported in the literature, and of the thirty-one patients two were free from recurrence six years later, while four are still under observation. One lived four years, two three years, three two years, and five lived one year, while seven died within a year. At the end of treatment the patients were instructed to report for examination every three months, and later every six months. The results of such treatment are said to be more encouraging in vulvar cancer than in vaginal cancer. Since cancer of the vulva is rare, the data so far obtained are scarcely sufficient to warrant a definite opinion, but from the few cures obtained, and the palliative effects produced, the author considers the employment of radium to be an indispensable method of treatment.

250. Temporary Operative Sterilization.

SERDUKOFF (*La Gynécol.*, September, 1929, p. 513) states that a conference held in 1928 of Russian gynaecologists expressed the opinion that temporary sterilization by surgical means is not justifiable except for urgent medical reasons. Nevertheless, he quotes the report of a Russian clinic in which during three years 75 operative sterilizations were performed in women aged from 26 to 34, the reasons being medical in one-third, economic in over one-third, and in one-fourth consisting solely in the patient's wish not to bear children. Serdukoff approves of operative sterilization on medical grounds, but does not regard it as justifiable as an alternative to repeated artificial abortions. Sterilization on social or eugenic grounds, he remarks, is not justifiable by joint agreement by patient and doctor; in such cases the necessity should only be admitted after a medical consultation which has confirmed it, and fixed the requisite duration of artificial sterility. The induction of temporary sterility by spermatotoxic injections, or those of corpus luteum extracts, or by radiological applications to the ovaries, is unsafe; such injections and radiation may injure the ovaries and germ cells, and the latter induces a sterility which may be lasting. Surgical treatment of the Fallopian tubes is the best method. Serdukoff describes the operation he prefers; he states that it can be performed after laparotomy or colpotomy, and on the gravid as well as the non-gravid uterus. A catgut ligature is tied round the tube two centimetres from the uterine end, and the tube is cut across distally. The proximal portion of the tube, freed by interstitial dissection in the myometrium, is removed, the uterine wound is sutured, and the distal end of the tube is implanted in the wall of the uterus as far as possible externally to the first wound. Serdukoff has employed this operation on medical grounds in thirty-four patients, whose average age was 32; none subsequently became pregnant.

Pathology.

251. Incidence of Undulant Fever in Pregnancy and Abortion.

E. L. CORNELL and C. R. DE YOUNG (*Amer. Journ. Obstet. and Gynecol.*, December, 1929, p. 840) have recently investigated the incidence of undulant fever in pregnancy and abortion in Chicago. The patients were from the middle and lower classes, and included whites, coloured people, and Mexicans, who lived in all parts of the city, and therefore presented a rough cross-section of the population. Blood specimens from 1,015 pregnant women were tested by the macroscopical agglutination method with polyvalent *Brucella abortus* and *Brucella melitensis* antigens. The cultures used for the antigens were *Br. abortus* 705 isolated in England, *Br. abortus* 456 isolated from a bovine foetus and supplied by the Washington Bureau of Animal Industry, *Br. melitensis* 803 isolated from a guinea-pig inoculated with goat's milk, and *Br. melitensis* 428 supplied by the Pasteur Institute of Algeria. Of the 1,015 blood serums, none gave definitely positive results and only five gave slightly positive reactions. Clinically these five patients were in good health, and there was no interruption of pregnancy; they had had no illness which suggested undulant fever. In addition to this series of cases twenty-three cases of abortion were studied, all except one proving negative to the agglutination test, and this exception giving only a weakly positive reaction with placental blood, in a dilution of 1 in 80, the venous blood being negative. In six cases cultures were made from the placental material. None yielded *Br. abortus* or *Br. melitensis*. Six other cases in which a clinical diagnosis of undulant fever was made or suspected by the patient's physician gave a positive agglutination test with formalinized antigens in dilutions of 1 in 300 to 1 in 2,000. Only one of these patients was a woman, and she had given birth to a normal child at full term three months before becoming ill, and had no history of previous abortion. The authors suggest that partly cooked meat and liver from infected cows and pigs may be a possible source of infection.

252. Br. abortus in Human Pathology.

M. KRISTENSEN (*Ann. de Méd.*, November, 1929, p. 339) states that from April 1st, 1927, to December 1st, 1928, specimens of serum from about 4,600 patients were examined at the Danish Serotherapeutic Institute, and in 500 cases agglutination with *Br. abortus* was found. The minimum titre was 1 in 100, but usually the reaction was much more marked (1 in 400, 800, or 1,600); 223 more cases of the kind were noted between December 1st, 1928, and June 1st, 1929. In most of the positive cases the deviation of the complement reaction also yielded a positive result. During the same period the serum of 148 patients agglutinated *B. typhosus* and of 190 patients *B. paratyphosus* B. Infection by *Br. abortus* is therefore at least as frequent in Denmark as enteric fever. Not a single one of the patients had been infected as the result of living in Mediterranean countries or other regions where Malta fever is prevalent, but the great majority had drunk raw cow's milk or cream, or had been in contact with cows suffering from contagious abortion; in only a minority of cases was no information available as to the source of contagion. The occurrence of the cases was almost always sporadic, but was naturally most frequent in the most populated areas. The much greater frequency of the incidence of the disease in men was shown by the fact that of the 500 patients 391 were men and 109 women. It was remarkably rare in young children, there being only one patient under the age of 6. The specific treatment employed in Denmark has been: (1) serum therapy, including the use of an Italian serum against Malta fever, and a serum prepared by injecting horses with Danish strains of *Br. abortus*; and (2) vaccine treatment with *Br. abortus*, either alone or in combination with other organisms such as staphylococci or typhoid bacilli. At the present time there appears to be a tendency to substitute vaccine treatment for serotherapy.

253. Atypical Plasmodia in Malaria.

G. VILLAIN (*Arch. de l'Inst. Pasteur de Tunis*, November, 1929, p. 352) has noted abnormal forms of haematozoa in patients with severe malarial infection, and records six cases in which such forms were found. There was an evident correlation between the intensity of the attack and the plasmodial aberration. The atypical forms were of two types. In one the organisms showed an extreme polymorphism, with the cytoplasm and chromatin most fantastically arranged. The chief characteristic of these was the multiple, disordered elongation of the whole plasmodial body; its arrangement in fine, long, contorted, and often anastomotic filaments suggested the *Plasmodium tenue* of Christophers. In the other type there were forms transitional between those just described and the classic rings of young schizonts. Pigment was absent from these atypical schizonts, and both normal and abnormal forms were noted in the same preparation. Only one of the patients had previously received quinine; plasmodiolysis due to this drug could not be assigned as a cause of the abnormalities. Villain believes that the atypical forms are due to a greater aggressiveness of the plasmodia, to a weakness of the host, or to an association of these. He does not think that they represent different species or subspecies, but that they are simply biological variations of the three common types, particularly of *P. falciparum*. He advises that the blood of all malarial patients, whether proved or suspected, should be most carefully examined, and considers that the presence of atypical plasmodia should be taken to indicate a grave prognosis and a call to intensify specific treatment, whatever the clinical symptoms may be.

254. Specificity of Soluble Toxins of Haemolytic Streptococci.

G. F. DICK and G. H. DICK (*Journ. Amer. Med. Assoc.*, December 7th, 1929, p. 1785), as the result of comparative observations and experiments with the soluble toxins produced by scarlet fever and by erysipelas *haemolytic streptococci*, came to the following conclusions. No direct relation was demonstrated between spontaneous immunity to scarlet fever and spontaneous immunity to erysipelas toxin. An attack of scarlet fever does not confer immunity to erysipelas. Artificial immunization with scarlet fever toxin produced immunity to scarlet fever without conferring immunity to erysipelas toxin. Erysipelas streptococci yield considerably weaker toxin than scarlet fever streptococci. Erysipelas antitoxin produced by immunizing against toxin from a single strain of erysipelas streptococcus neutralizes the homologous toxin and toxins from other strains of erysipelas streptococci, but does not neutralize scarlet fever toxins. Scarlet fever antitoxins obtained from one strain of scarlet fever streptococcus neutralizes the homologous and other scarlet fever toxins, but does not show any cross-neutralization with erysipelas toxins. The soluble toxins produced by scarlet fever and by erysipelas haemolytic streptococci are immunologically specific and distinct.

"OSTELIN" VITAMIN D

PREPARATIONS AND PRICES

OSTELIN LIQUID

(Ostelin Liq.) Ostelin vitamin D suspended in glycerin.

Three minims equal in vitamin D potency one drachm of cod-liver oil. Tasteless, it may be given in water or milk, on sugar or in mixtures.

DOSE.

Children, 1-4 drops; Adults, 3-5 drops, t.d.s.p.c.

8 c.c. phials - - 2/6

OSTELIN TABLETS

(Tab. Ostelin Co.)

These tablets are a combination of calcium and Ostelin vitamin D. Sugar-coated, equalling Ostelin Liq. m.3 and Calc. Glycerophos. gr. 2 Disintegrate readily.

DOSE.

Children, 1-3 daily; Adults, 1-3 thrice daily.

45 tablets - - - 2/6

OSTOMALT

(Ext. Malti c Ostelin Co.) Ostelin with Malt Extract and Orange Juice.

Containing vitamins A, B, C and D, together with calcium glycerophosphate. One teaspoonful contains the vitamin D equivalent of half-a-teaspoonful of cod-liver oil with orange juice, and 0.5% of Calc. Glycerophos.

DOSE.

Children, ½-1 teaspoonful; Adults, 1-3 teaspoonfuls.

1lb. & ½lb. jars 4/- & 2/6

OSTELIN EMULSION

(Emuls. Ostelin Co.)

A very palatable emulsion containing Ostelin vitamin D equal to 50% of cod-liver oil, and 0.5% Calc. Glycerophos.

DOSE.

Children, ½-1 teaspoonful; Adults, 1-3 te spoonfuls.

In 8-oz. bottles - 2 6

ALSO

COLLOIDAL CALCIUM with Ostelin vitamin D Ampoules. For subcutaneous injection. 1 c.c. ampoules, 6 in a box - 5/-

OSTELIN with PARATHYROID TABLETS *(Tab. Ostelin c Parathyroid.)* Sugar-coated tablets = Ostelin Liq. m.3, Parathyroid Sicc. gr. 1/40th, Calc. Glycerophos. gr. 2. Bottles of 100 tablets - - 8/9

OSNOL Nasal spray. A solution of Ostelin vitamin D in neutral petroleum, for use in catarrhal conditions of the nose. 1 oz. bottles - 3/-

The above prices are subject to the usual professional discount. Any request for further information should be directed to

GLAXO LABORATORIES, LONDON, N.W.1

★ Vitamin D, the antirachitic or calcifying vitamin, ranks first in importance in calcifying processes. If there is an abundance of this substance present in the diet, well calcified teeth will be formed. . . . .

"Without vitamin D perfect calcification will not take place, however much calcium and phosphorus is given in the diet."

Sunshine Glaxo is a fully humanised milk food containing added vitamin D in biologically standardised quantity. Eighteen months' results in general practice now confirm two years' clinical trials and widely demonstrate the value of this new and improved formula, which has successfully applied the latest scientific developments to infant feeding.

This new formula has the further advantage of avoiding the constipation so frequently associated with the artificial feeding of infants.

A trial supply will gladly be sent to yourself or your patient on request to:

THE ONLY SUPPORT

Giving direct abdominal uplift

Maintained in any position that the patient may assume without any cramping or binding of the hips whatsoever. The principle is that of a direct anterior-posterior pressure, and enjoys numerous advantages over any other make of support on the market. It is simply fastened by a strap and buckle, and can be adjusted to any degree that the physician may prescribe.

For full particulars apply to:

H. E. CURTIS & SON, LTD.

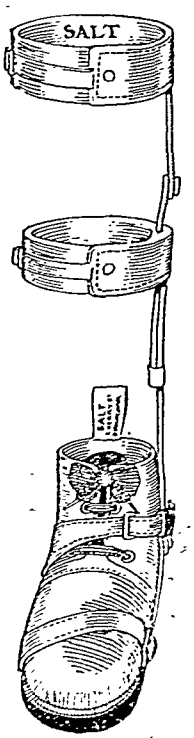
Salt and Son Ltd.

SALT'S PATENT VARUS BOOT

WITH LEG INSTRUMENT

Note the Divided Construction



In most cases of Talipes Varus the ankle goes over outwardly, the patient walking on the outer border of the foot. Also, there is a tendency for the limb, from knee downwards, to rotate inwardly.

It is of extreme importance that these features should be corrected in the early stages, such correction being achieved as follows—

1. The back of the foot can be held firmly by the boot, the loose front portion holding the toes everts the front portion of the foot by strap traction.
2. The "T" strap pulls the ankle-joint comfortably and easily into correct position when fastened over the leg instrument.
3. Finally, the leg instrument, when carried above the knee-joint, prevents the internal rotation of the leg from below the knee.

Thus the foot and leg are held in normal position, allowing the child perfect freedom in walking.

Where extra lightness is required (as in the case of a young child) the instrument can be made in duralumin, which has the advantage of being half the weight of steel.

System II.

BELT FOR GENERAL SUPPORT.

Pre-eminently useful after confinement, affording the most effectual support to the internal organs, preventing pressure on the fundus of the womb.

System II should be used in all cases where the abdominal muscles need support. It also invariably gives good results in cases of enteroptosis, gastroptosis, and all similar troubles.

JAEGER
Pure Wool

K K UNDERWEAR.

Even Medical Men do get Colds.

That is why Jaeger, with its special health-preserving properties, appeals to the Profession. There are many excellent varieties of Jaeger Underwear, but KK is particularly mentioned as being most suitable. The weight, for instance, is medium; it has been carefully chosen and does not vary, which is a vital consideration; while the wool, which is wonderfully soft and gives real comfort, is also hard-wearing.

SOCKS THAT ARE BETTER

There's one big reason why the Two Steeples No. 83 Socks are so good. They are made from St. Wolstan Wool, the highest grade pure botany wool that can be bought. That accounts for their better wear and greater comfort.

Then you have choice of over thirty handsome ingrain shades, a shade for every suit. Skilful dyeing and blending of the super wool provides heathers, browns, greys, lovats, etc., full of tone and character. Always ask your hosier for

APPEARANCE is everything to the professional man, as nothing enhances status so much as good attire.

Most tailors study price, fit and finish, but few care what happens to your clothes after purchase, whereas Keith Bradbury, Ltd. provide a FREE VALET SERVICE for the care of their customers' clothes after purchase; garments are collected, brushed, repaired, sponged, pressed and returned like new.

Every consideration is given to the financial convenience of Doctors, who, more often than not, have to wait indefinitely for settlement of their own accounts. Arrangements are made whereby accounts can be disposed of half-yearly, quarterly, upon a £1 per month basis, or in any other way to suit individual requirements.

Distance need be no barrier to country practitioners, as the comprehensive Keith Bradbury self-measurement chart assures a perfect fit of all West End garments supplied by post—and to convince you that our confidence in this through-the-post service is not misplaced, we undertake to give you complete satisfaction or re-make the garments ordered.

An illustrated catalogue, patterns or full particulars of our special financial facilities will be gladly sent upon receipt of a postcard or telephone message, or perhaps you prefer to call and see us.

Also in exactly similar form and price—

SOLID IODINE

A Remarkable advance in the presentation of H_2O_2

Owing to the rapidity in which H_2O_2 ordinarily loses its strength, it has not usually been practicable to carry a supply about without risk of frequent replacement; also, of course, of breakage.

Now a new process has been introduced of presenting Peroxide of Hydrogen in a solidified form, so as to enable it to be included conveniently in the physician's or surgeon's everyday case of instruments, etc.

This Solidified Peroxide of Hydrogen is known under the trade name of 'Peroxtik.' It is guaranteed to maintain its original 10-volume strength for a reasonable period.

A full-size tube of this new product will gladly be sent to the Medical Profession FREE on application to the Medical Dept., Messrs. ARTHUR H. COX & CO., LTD., 93, Lewes Road, Brighton, or can be purchased from the usual sources, at the cost of 1/3.

'Peroxtik'

FOR MENTAL DISORDERS,
NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

Medical Superintendent: DANIEL F. RAMBAUT, M.A., M.D.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE.

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK.

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit-growing.

BRYN-Y-NEUADD HALL.

The seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 56, Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, EXETER,
SOUTH DEVON.

For the care and treatment of Ladies suffering from Mental Diseases. Limited to eight patients. Telephone: Starcross 19.

CLIFFDEN, TEIGNMOUTH, in connection with Court Hall, for early and convalescent cases. Cliffden is a large well-appointed house, with lovely views of the South Devon Coast. It is beautifully situated in grounds of 19 acres. The gardens are very attractive, and there is a private road to the beach.

Resident Physicians: BERTHA M. MULES, M.D., B.S.; ANNIE S. MULES, M.R.C.S., L.R.C.P.
Telephone: *Teignmouth* 289.

HAYDOCK LODGE,
NEWTON-LE-WILLOWS, LANCASHIRE.

'Phone: 11 Ashton-in-Makerfield.

For the reception and treatment of PRIVATE PATIENTS of both sexes of the UPPER AND MIDDLE CLASSES either voluntarily or under Certificate. Patients are classified in separate buildings according to their mental condition.

Situated in park and grounds of 400 acres. Self-supported by its own farm and gardens, in which patients are encouraged to occupy themselves. Every facility for indoor and outdoor recreation. For terms, prospectus, etc., apply MEDICAL SUPERINTENDENT.

BELVOIR NURSING HOME,
ASTON-ON-TRENT, DERBY.
FUNCTIONAL NERVOUS DISORDERS & CHRONIC MEDICAL CASES.

The Home, a Georgian mansion, 14 miles from Nottingham and 6 miles from Derby, is for both sexes. In addition to the methods of general medicine, Psycho-Therapeutic treatment is used extensively in suitable cases. Certifiable cases are not received. Electrical treatment, Radiant Heat, X-ray, and Ultra-violet Light is available in the Nursing Home. Billiards, tennis, etc. Fees from 5 to 12 guineas per week; for Chronic Medical Cases from 3 guineas a week. For further particulars apply to—

Dr. E. M. DOUGLAS-MORRIS, ASTON, DERBY. *Telephone*: Shardlow 16.

THE COPPICE, NOTTINGHAM.
HOSPITAL FOR MENTAL DISEASES.

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Voluntary Boarders received without Certificates.

Tel.: 64117. *For terms, etc., apply to the Medical Superintendent.*

The MAUDSLEY HOSPITAL
DENMARK HILL, S.E.5.

Telephone: RODNEY 4841—2.

A CLINIC instituted by the London County Council for Treatment of NERVOUS and CURABLE MENTAL DISORDER. Voluntary patients ONLY RECEIVED.

OUT-PATIENTS—2 p.m.: MEN—Mondays and Thursdays. WOMEN—Tuesdays and Fridays.
IN-PATIENTS: (*a*) 164 beds (both sexes) in wards or separate rooms. (*b*) 15 private rooms (for ladies) with special sitting room, garden, and dietary.

Terms:

(*a*) **£5 a week, but in case of patients with a legal settlement in the County of London a less sum may be charged according to means.**
(*b*) **£6 6s. a week.**

Terms include (with rare exceptions) all forms of treatment, for which exceptional facilities exist—there being a staff of consultant specialists and the central laboratory of London County Mental Hospitals being attached to the hospital. Inquiries of EDWARD MAPOTHER, M.D., M.R.C.P., F.R.C.S., Medical Superintendent.

WONFORD HOUSE HOSPITAL,
EXETER, DEVON.

Telegrams: Exeter 2642. *Telephone*: Exeter 2642.

Salary attached to this appointment is at the *rate of* £140 per annum, together with board, residence, and laundry.

Applications, stating age, qualifications, and experience (Ophthalmology desirable), accompanied by testimonials, should be sent to the *undersigned* as early as possible.

ARTHUR L. BOURNE,
March 4th, 1930. *Secretary-Supt.*

The Northern Infirmary, INVERNESS.

Wanted for *April 1st next*, HOUSE PHYSICIAN and JUNIOR HOUSE SURGEON (combined post), fully qualified and registered, male, unmarried. Salary £100 per annum, with board, residence, and laundry.

Applications, *stating age, medical school*, qualifications, and experience, with copies of recent testimonials, to be sent before 22nd inst., to Mr. ROBERT GILBERT, Hon. Secretary to the Institution, 20, Church Street, Inverness.

March 3rd, 1930.

Liverpool Hahnemann Hospital, HOPE STREET.

Applications are invited for the post of RESIDENT MEDICAL OFFICER to the above Hospital, which falls vacant on March 25th. Appointment is for six months, renewable. Salary at the rate of £100 p.a. Knowledge of *Homœopathy desirable but not essential. Duties* include casualties, occasional anæsthetics, and assisting at operations.

Apply, stating age, sex, experience, and enclosing copies of recent testimonials, to the *REGISTRAR* before March 17th.

East Suffolk and Ipswich HOSPITAL.
(265 Beds—7 Residents.)

Applications are invited for the posts of *Two HOUSE SURGEONS (male, British)*. Salary for each appointment at the rate of £120 per annum, with board, residence, and laundry.

Applications, stating age, qualifications, and experience, and accompanied by three recent testimonials, to be sent to the undersigned.

The Hospital, *ARTHUR GRIFFITHS*,
Ipswich. Secretary.

Ear and Throat Hospital, BIRMINGHAM.

HOUSE SURGEON wanted, with clinical experience, and also in administering anæsthetics. Salary at the rate of £150 per annum, with board and residence. Duties to commence April 1st. Appointment for six *months, to* September 30th, when one of the other *House* Surgeon appointments will be vacant.

Applications and testimonials to be forwarded on or before March 18th to the under-signed.

S. G. GREW,
February, 1930. Secretary.

Westminster Hospital, Broad Sanctuary, S.W.1.

Applications are invited for the office of ASSISTANT MEDICAL REGISTRAR. The post is a whole-time one, and the salary attached to the office is *at the rate of* £100 per annum.

Candidates should have held a resident post at a General Hospital.

The appointment is of six months' duration.

Applications should be submitted to the undersigned not later than *Saturday, March 15th*.

CHARLES M. POWER, Secretary.

Westminster Hospital, Broad Sanctuary, S.W.1.

There will be a vacancy in the office of *SENIOR RESIDENT AND CASUALTY OFFICER* for duty commencing April 1st next.

The appointment is for six months and may be renewed for a further *period of six months*.

Candidates should have previously held a resident appointment. Salary £104 per annum, with board-residence.

Applications should be submitted to the under-signed not later than *Saturday, March 15th*.

CHARLES M. POWER, Secretary.

King's College Hospital, Denmark Hill, London, S.E.5.

Applicants are invited for the appointment of MEDICAL OFFICER in charge of the Female Gonorrhœa Department. Applications, stating qualifications and experience, accompanied by not more than four recent testimonials, to be sent on or before March 15th to the House Governor, from whom particulars as to salary, and duties can be obtained.

City of Nottingham.

APPOINTMENT OF RESIDENT MEDICAL SUPERINTENDENT, NOTTINGHAM CITY INFIRMARY.

The Nottingham City Council invite applications from duly qualified persons (preferably married) for the appointment of Resident Medical Superintendent at the Nottingham City Infirmary.

Salary £900 per annum, rising (subject to satisfactory service) by two annual increments of £50 to a maximum of £1,000 per annum. An unfurnished house, with light, fuel, and laundry will be provided but this will not include food or servants.

The above-mentioned salary is inclusive of all duties and the person appointed will not be allowed to engage in private practice.

The appointment will be subject to the approval of the Ministry of Health.

Applicants, in addition to possessing the usual professional qualifications, must (1) have held the position of House Physician or House Surgeon in a public General Hospital, and (2) have had considerable experience as a Medical Officer in a Poor Law Infirmary or similar Institution.

Further particulars as to the terms of the appointment and of the duties to be performed in connection therewith may be obtained on application to me, the undersigned, and the successful candidate will be deemed to have had notice of and to have accepted such terms.

The appointment will be subject to the Superannuation Scheme in force, and the successful candidate will be required to pass a medical examination.

Applications, stating age, qualifications, and full particulars of present and past experience, together with copies (which will not be returned) of not more than three recent testimonials, endorsed "Resident Medical Superintendent," to be delivered at my office not later than first post on Wednesday, March 19th next.

Canvassing, whether directly or indirectly, is prohibited and will be deemed a disqualification.

Dated this 28th day of February, 1930.

Guildhall, Nottingham. W. J. BOARD, Town Clerk.

Cardiff Royal Infirmary.

(Associated with Welsh National School of Medicine.)

Applications are invited for the post of HOUSE SURGEON to the Ophthalmic Department of the above Institution. The post is tenable for six months, but may be extended for a further six months. This post is open to ladies.

Salary is at the rate of £75 per annum, with board-residence. Candidates must have experience of Refractions.

Application forms may be obtained from the undersigned, and should be returned completed, with copies of recent testimonials, at the earliest possible date, as the appointment commences immediately.

R. ARMSTRONG, March 3rd, 1930. Medical Supt.

Hove Hospital (Carr-Burton MEMORIAL), Sackville Road, HOVE.

A RESIDENT MEDICAL OFFICER (male) is required, who must be unmarried and under 40 years of age. The Hospital contains 24 beds.

The appointment affords excellent opportunity for Surgical experience and for acquiring knowledge of Radium treatment.

Salary £150 per annum, with board, apartments, and laundry.

Candidates should state when they could take over the duties.

Expenses not exceeding one guinea will be paid to any applicant invited to attend for interview.

Applications must be sent in by March 22nd, addressed to the General Secretary, 113, Queen's Road, Brighton.

St. John's Hospital, Lewisham, S.E.13.

There is a vacancy for a RESIDENT MALE HOUSE SURGEON, to commence duty on April 1st. Remuneration £100 p.a. Applications, with copies of testimonials, should be sent to the Secretary of the Hospital not later than Friday, March 14th.

Leeds Public Dispensary.

Wanted, JUNIOR RESIDENT MEDICAL OFFICER. Salary £150 per annum, with board, residence, and laundry. Separate sitting room. Applications, with copies of three recent testimonials, to be addressed to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.

Metropolitan Borough of SHOREDITCH.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH.

The Borough Council invite applications for the appointment of an Assistant Medical Officer of Health.

The salary will be at the rate of £650 per annum, rising by annual increments of £25 to a maximum of £750 per annum. No bonus will be payable.

Candidates must be duly qualified and registered as Medical Practitioners, must have had experience in Maternity and Child Welfare work, and possess a Diploma in Public Health. Preference will be given to those who have held a resident appointment in a Children's Hospital, and had experience in Artificial Light Treatment. The person appointed will be required to devote the whole of his or her time to the duties of the office, to act under the administrative control and supervision of the Medical Officer of Health, and to pass a medical examination as to physical fitness for the position. The appointment will be subject to the approval of the Ministry of Health, and to the provisions of the Shoreditch and Other Metropolitan Borough Councils (Superannuation) Act, 1922.

Applications, on printed forms to be supplied, and accompanied by copies of not more than three recent testimonials, must reach the undersigned not later than noon on March 31st, endorsed "Assistant Medical Officer of Health."

The Council will proceed to make the appointment at their meeting on Tuesday, April 15th.

Shoreditch Town Hall, Old Street, E.C.1. March 4th, 1930. R. CYRIL RAY, Town Clerk.

Lowestoft and North Suffolk
HOSPITAL, LOWESTOFT.

JUNIOR HOUSE SURGEON (male) required. Salary £120 per annum, with board, residence, and laundry. Duties to commence in April. Applications, together with copies of three recent testimonials, to be sent to the Honorary Medical Superintendent.

West London Hospital,
Hammersmith, W.6. (234 Beds.)

Applications are invited for the post of HONORARY MEDICAL REGISTRAR for a period of one year, eligible for re-election annually for a total period of not more than three years. An honorarium at the rate of £100 per annum is attached to the post. The successful candidate must hold no appointments at a General Teaching Hospital during his term of office. The duties include the preparation of the Medical Registrar's Report for the year and the supervision of the records of cases. The candidate appointed must be available as substitute for the Physicians and Assistant Physicians when required, and be prepared to undertake such teaching for the Post-Graduate College as the Board may approve.

Candidates are required to be registered under the Medical Act. Applications, with copies only of testimonials, must reach me not later than Thursday, March 20th. Candidates must attend the Meeting of the Medical Council on Friday, March 21st, at 4.45 p.m., and prior to that date call upon and send copies of application and testimonials to each member thereof. They must not canvass members of the Board, but nevertheless must send copies of their application and testimonials to each member thereof, and, if so notified, be in attendance at a Meeting of the Board at 5 p.m. on Tuesday, March 25th, when the election will be made.

H. A. MADGE, Secretary.

West London Hospital,
Hammersmith, W.6. (234 Beds.)

Applications are invited for the post of HONORARY ASSISTANT SURGEON. Candidates must be Fellows of one of the Royal Colleges of Surgeons of England, Edinburgh, or Ireland. The successful candidate will be required, in addition to other duties, periodically to deliver Surgical Courses of Lectures to the Nurses and to undertake such teaching for the Post-Graduate College as the Board may approve.

Applications, with copies only of testimonials, must reach me not later than Thursday, March 20th. Candidates must attend the Meeting of the Medical Council on Friday, March 21st, at 4.30 p.m., and prior to that date call upon and send copies of application and testimonials to each member thereof. They must not canvass members of the Board, but nevertheless must send copies of their application and testimonials to each member thereof, and, if so notified, be in attendance at a Meeting of the Board at 5 p.m. on Tuesday, March 25th, when the election will be made.

H. A. MADGE, Secretary.

West London Hospital,
Hammersmith, W.6. (234 Beds.)

Applications are invited for the post of HONORARY OBSTETRIC REGISTRAR. The holder of the post is eligible for re-election annually for a total period of not more than three years. The duties include the preparation of the Obstetric Registrar's Report for the year and the supervision of the records of cases. The candidate appointed must be available as a substitute for the Surgeon and Assistant Surgeon for Diseases of Women and for emergency operations when required, and be prepared to undertake such teaching for the Post-Graduate College as the Board may approve.

Candidates are required to be registered under the Medical Act. Applications, with copies only of testimonials, must reach me not later than Thursday, March 20th. Candidates must attend the Meeting of the Medical Council on Friday, March 21st, at 4.45 p.m., and prior to that date call upon and send copies of application and testimonials to each member thereof. They must not canvass members of the Board, but nevertheless must send copies of their application and testimonials to each member thereof, and, if so notified, be in attendance at a Meeting of the Board at 5 p.m. on Tuesday, March 25th, when the election will be made.

H. A. MADGE, Secretary.

London Hospital, E.1.

Applications are invited for the post of DIRECTOR of the Department for Venereal Diseases. Candidates must be fully qualified and must possess special knowledge and experience of the diagnosis and treatment of these diseases.

The salary for the post is £800 a year, and the Director will be required to devote not less than 30 hours a week to the work of the Department.

Applications and testimonials should be submitted by March 14th.

Further particulars may be obtained from the undersigned.

Full particulars on application to Mr. Percival Turner.

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(FOUNDED 1880.)

12, Stratford Place,

Tele. Address: Triform, Wesdo—London. Oxford Street, W.1. Telephone: Mayfair {1782 1783}

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the BRITISH MEDICAL ASSOCIATION has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

Members of the British Medical Association may take advantage of a reduced scale of charges applicable to them.

The business undertaken by the British Medical Bureau is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the British Medical Bureau. Vendors may depend upon receiving introductions only to eligible and bona-fide purchasers. All information is treated in strictest confidence. Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the British Medical Bureau to ensure that only the most Trustworthy and Reliable Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the British Medical Bureau. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The British Medical Bureau has its own staff of fully qualified Accountants wholly engaged on medical work—i.e., Investigation of Practices for purchasers, Income Tax, Auditing Books & Accounts, etc.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges.

1. WITHIN FIFTY MILES OF LONDON.—In a small Country Town in pretty district, a well-established PRACTICE averaging over £700 p.a., including panel of 538, and appts. worth about £60. Visits 3/6 to 21/-, medicine extra. Midwifery discouraged. Railway station in place. Very good house (3 reception, 5 bedrooms, etc.), with large garden, tennis court. Garage. Electric light. Price for freehold £3,000. Premium £1,050. Exceptionally good educational facilities for boys.
2. LARGE UNIVERSITY CITY (WEST).—Good-class old-established non-dispensing PRACTICE worth last year £1,274, including select panel of about 350. Visits up to 21/-. Very little midwifery. Good house in best part of City, overlooking park and containing ample accommodation. Vendor's freehold, but will be let on lease. Premium only £1,200.
3. CAMBS.—Old-established Country PRACTICE, averaging for the past three years over £1,200 p.a. Panel of 870. Visits 5/- upwards, medicine extra. About 30 cases of midwifery from 2 to 3 gns. Nice house, with 2 reception, 6 bedrooms, etc., and garden. Rent on lease £80 p.a. Premium £1,800.
4. PARTNERSHIP.—In a most desirable outlying residential suburb a suitable Partner (University Graduate, experienced, 30 to 35 years of age and married preferred) can acquire a share (producing at first about £1,200 p.a., but larger might be considered, with further shares up to a third at arranged intervals) in an old-established good mixed-class Practice, averaging over £10,000 p.a. Very good house, with ample accommodation, garden, etc., on rental. Premium 2 years' purchase. Short preliminary assistantship essential.
5. PARTNERSHIP.—LONDON, S.W.—PLEASANT RIVERSIDE SUBURB.—A one sixth share is offered in an old-established mainly better-class Practice, rapidly increasing, and with scope for still further development. Average gross cash receipts for past two years £6,213 (last year £6,652). Panel of over 5,000. Fees 3/6 to 21/-. Mid. 3 to 20 gns. Very good house, with 5 to 6 bedrooms, etc. For sale or might be rented. Premium 2 years' purchase.
6. BORDERS OF LINCS AND YORKS.—PRACTICE is old-established, mainly agricultural, situated in pleasant district. Receipts average over £840 p.a. Panel produces nearly £300, and appointments £70. Fees from 3/-. Nice house, well situated, containing 2 reception, 4 bedrooms, etc. Three acres of garden. Rent on lease £56 p.a. Very low expenses. No local opposition. Premium 1½ years' purchase.
7. PARTNERSHIP.—WITHIN 100 MILES OF LONDON.—A one-fourth share can be acquired in a very good non-dispensing mainly better-class Practice, in a large town, at present worked by three partners, who now require further assistance. Gross cash receipts average over £8,500 p.a. Panel of 700. Fees 5/- to 21/-. Suitable house obtainable. Graduate preferred, aged 30 to 35, and experienced in anæsthetics. Premium £4,000.
8. [illegible] good mixed-class PRACTICE in beautiful town. Receipts for last twelve months increasing. Fees 3/6 to 20/-. Excellent containing 2 reception, 6 bedrooms, etc. Rent on lease £65 p.a. Premium £1,800.
9. SOUTH-EAST COAST.—PARTNERSHIP.—A one-third share (with increase later) in an old-established non-dispensing non-panel Practice, in favourite residential resort. Gross cash receipts average over £3,000, with good scope. Fees 5/- to 21/-. Good corner house, with 6 bedrooms, etc. Can be purchased or rented. Premium 2 years' purchase. Scope for surgery if desired.
10. LONDON, S.W.—Very old-established chiefly middle-class PRACTICE, rapidly increasing and offering still further scope. Gross cash receipts for the immediate past twelve months approximately £5,000. Panel of about 1,500; could be much increased. Fees from 2/6 to 21/-. Two houses available, on rental. Very suitable for two friends in partnership. Premium 1½ years' purchase.
11. WITHIN 100 MILES OF LONDON.—PARTNERSHIP.—Third share of old-established mixed-class and increasing Practice in small pleasant market town in an agricultural district. Cash receipts last year over £3,100, including appts. worth £300 and panel with mileage producing £500. Visits 3/6 to 15/-. Opposition slight. Railway station. Compact house (consulting and waiting rooms, 2 sitting, 5 bedrooms, dressing and bathroom, etc.). Garden. Garage. Price, freehold, £900. Premium 2 years' purchase.
12. SUSSEX.—Unopposed old-established Village PRACTICE in delightful surroundings, producing about £1,100 p.a., including panel of 545, and capable of considerable increase. Exceptionally charming residence standing in 3½ acres of well-laid-out garden, tennis court, etc., and containing lounge hall, 2 reception, 7 bedrooms (3 fitted h. & c. water basins, dressing and 2 bathrooms, etc. Central heating. Electric light. Garage. Price, freehold, £3950. Premium £1,650.
13. YORKS.—LARGE TOWN.—Very old-established middle and working-class PRACTICE, offering exceptional scope for increase. Income for last year £1,500, including panel of over 1,700. Visits 4/6 to 5/-. Conveniently situated house, with 2 reception, 4 bedrooms, etc. Rent on lease £56 p.a. Premium £2,250. Ill health reason for sale.
14. HOME COUNTY.—Near Sea.—Old-established unopposed Country PRACTICE in pretty district. Receipts last financial year £1,113, including union, etc., £55, and panel 400. Railway station near. Good house in own grounds (about one acre, but more can be had if wished), containing 2 reception, 6 bedrooms, etc. Water laid on and electric light available. Price, freehold, £1,650. Premium £1,625. Educational facilities and sport.
15. LONDON, W.—Chiefly middle-class PRACTICE, averaging about £700 p.a., including panel of 750. Visits 3/6, 5/-. No midwifery. Suitable house, with 4 beds., etc. Rent on lease £96 p.a. Prem. £750.
16. PARTNERSHIP.—OXON.—Delightful residential district near good town.—A one-third share (to commence with) in an old-established good mixed-class Practice, averaging for the past three years £1,540, and offering good scope. Panel of nearly 1,000. Fees 3/6 to 21/-. Choice of two houses at rentals of £100 and £50 p.a. Sport of all kinds. Premium 2 years' purchase.
17. SOUTH DEVON.—PARTNERSHIP.—Attractive Town [illegible] to Sea.—A half share in a very old-established and rapidly increasing mixed general Practice. Average cash receipts for last 3 years £2,727, last year £3,521. Panel of 1,130. Fees 3/6 to 21/-. Good house in its own grounds with ample accommodation. Price freehold £1,900, £1,200 on mortgage. Premium £2,300. Cottage Hospital, and good scope for major surgery.
18. BORDERS OF NORTHANTS AND LINCS.—Unopposed old-established Country PRACTICE, within easy reach of large town, and worth over £1,500 p.a., including panel (with mileage) £675, and appts about £80. Visits 5/- to 20/-. Suitable house available. Rent £70 p.a., or can be bought. Premium 1½ years' purchase. Held by Vendor, who is retiring, over 30 years. Sport of all kinds.
19. NEAR LIVERPOOL.—Mainly better working-class PRACTICE, producing about £700 p.a., including panel of 854. Fees 2/6 to 5/-. Mid. 3 to 5 gns.; about 20 cases yearly. Suitable house available on rental. Premium £1,000.
20. LIVERPOOL.—Middle and working-class PRACTICE. Receipts for immediate past twelve months £1,247, including panel of 602. Fees from 2/6. Suitable house, with 2 reception, 4 bedrooms, etc. Large garden. Price for leasehold £1,550, of which £1,300 could remain on mortgage. Premium £1,550.
21. LONDON, S.W.—Old-established middle-class PRACTICE, producing over £1,000 p.a., including small panel of 320. Fees 2/6 to 7/6. Mid. lately refused. Good corner house, with ample accommodation. Rent on lease £115 p.a. Premium 1½ years' purchase.
22. SOUTH COAST.—FAVOURITE HEALTH RESORT.—Old-established mixed-class PRACTICE, producing about £1,000 p.a. Small panel of 283. Fees from 2/6. Suitable house, with 3 reception, 5 bedrooms, etc. Large garden. Price for leasehold £1,400, £1,250 on mortgage. Premium £1,200.
23. YORKS.—(North Riding).—Country PRACTICE in beautiful district. Average income over £750, including panel of about 330. Fees 3/6 to 21/-, medicine extra. Nearest opponent 4 miles. Suitable house with 2 reception, 4 bedrooms, etc., and garden of 1 acre. Rent on lease £30 p.a. Prem. 1½ years' purchase, part by instalments.
24. MANCHESTER DISTRICT. — Old-established middle and working-class PRACTICE, worth last year about £700, including panel of 590, and capable of increase. Expenses small. Well-situated house, with 6 rooms in addition to professional rooms. Large garden. Price, freehold, £250. Moderate premium accepted.
25. KENT.—Old-established Country PRACTICE, in favourite locality, and within 5 miles of the coast. Income for past 12 months £1,185, and increasing. Visits 5/- to 21/-. Panel of about 330. Appts. worth about £50 p.a. Convenient house, with ample accommodation. Nice garden. Price for freehold £1,800. Premium 1½ years' pur.
26. YORKS.—PROSPEROUS LARGE TOWN.—Well-established compact PRACTICE, averaging nearly £1,600 p.a., including panel of 1,400. Fees 3/- upwards. Not much midwifery. Low expenses. Very well situated double-fronted house, 2 reception, 4 bedrooms, etc., and good professional accommodation. Garden. Price for freehold £1,500 (£1,000 on mortgage). Premium 1½ years' purchase.
27. YORKS.—LARGE TOWN.—Old-established mainly working-class PRACTICE, producing over £1,200 p.a., including panel of over 1,400. Fees 2/6 to 5/-. Well-situated house, with good garden. Price £1,500. Premium £1,200.
28. LONDON, S.W.—A HALF SHARE, with succession in about 2 years, is offered after preliminary assistantship in a good mixed-class non-panel Practice, producing last year over £2,300. Fees 5/- upwards. Not much midwifery. Suitable flat or rooms available. Premium 2 years' purchase.
29. SOUTH AFRICA.—HEALTH RESORT (Inland Spa).—Old-established increasing PRACTICE (held over 20 years) on a main line of rail and in a healthy pleasant township much frequented by visitors in the Season. Cash receipts average over £1,750 p.a., including several appts. One opponent. Price for house £1,250, to include furniture, instruments, and motor car (original cost £2,000), and for goodwill £1,250, part by instalments. Efficient introduction. A knowledge of Hydrology would be a big asset.
30. NEAR WORCESTER.—Old-established Country PRACTICE, averaging over £1,000 p.a., including panel of about 600. Fees 2/6 to 10/6. Good house, with ample accommodation. Rent on lease £85 p.a. Premium £1,350, £1,000 down, balance easy instalments.

A NEW PREPARATION

'Collosol' IODINE & BLACK CURRANT PASTILLES

A desire has been expressed by many members of the medical profession for an antiseptic, astringent and palatable pastille and specially suitable for children as well as adults.

Accordingly, 'Collosol' Iodine and Black Currant Pastilles are now available. Each contains approximately $\frac{1}{10}$th grain iodine, as 'Collosol' Iodine, with the true fruit juice of the black currant.

Most Valuable and effective in all mouth and throat conditions

Greatly appreciated for their delightful flavour

'Collosol' Iodine and Black Currant Pastilles similarly to the 'Collosol' Iodine Pastilles, combine efficiency with complete freedom from undesirable after effects.

Samples, obtainable on application, will enable practitioners to confirm from a clinician's standpoint, the special attributes of 'Collosol' Iodine and Black Currant Pastilles.

Price 1/3 per Box.

HORMOTONE
BRAND

in disorders of the

CATAMENIA

and the

MENOPAUSE

Hormotone supplies the physiological stimulus to the endocrine glands, whose functional activity determines the normal catamenial flow.

When these internal secretions begin to fail at the period of the menopause, Hormotone acts both by substitution and homostimulation.

Dose: One or two tablets three times daily.

40, GLOUCESTER PLACE, PORTMAN SQUARE, LONDON, W.1

HUGH MACLEAN M.D., D.Sc., F.R.C.P.

MODERN VIEWS ON

DIGESTION and GASTRIC DISEASE

Second Edition Revised, 12s. net.

BRITISH MEDICAL JOURNAL:
"It is not surprising that Prof. Maclean's volume ... has rapidly passed into a second edition."

PRACTITIONER:
"It presents an excellent résumé of present-day knowledge, and the author's experience enables him to give ... practical advice on diagnosis and treatment."

MEDICAL TIMES:
"We welcome the [illegible] of a second edition. As an up-to-date work on this branch of medicine Prof. Maclean's book holds a premier place."

CANADIAN JOURNAL OF MEDICINE AND SURGERY:
"This concise, readable, and modern book can be fully commended to the practitioner wherever English is read."

CONSTABLE & CO LTD

SPRING WEAR for DOCTORS

£1 PER MONTH

APPEARANCE is everything to the professional man, as nothing enhances status so much as good attire.

Most tailors study price, fit and finish, but few care what happens to your clothes after purchase, whereas Keith Bradbury, Ltd. provide a FREE VALET SERVICE for the care of their customers' clothes after purchase; garments are collected, brushed, repaired, sponged, pressed and returned like new.

Every consideration is given to the financial convenience of Doctors, who, more often than not, have to wait indefinitely for settlement of their own accounts. Arrangements are made whereby accounts can be disposed of half-yearly, quarterly, upon a £1 per month basis, or in any other way to suit individual requirements.

Distance need be no barrier to country practitioners, as the comprehensive Keith Bradbury self-measurement chart assures a perfect fit of all West End garments supplied by post—and to convince you that our confidence in this through-the-post service is not misplaced, we undertake to give you complete satisfaction or re-make the garments ordered.

An illustrated catalogue, patterns or full particulars of our special financial facilities will be gladly sent upon receipt of a postcard or telephone message, or perhaps you prefer to call and see us.

CANCER OF THE RECTUM

ITS PATHOLOGY, SYMPTOMATOLOGY, AND TREATMENT.

BY

W. ERNEST MILES, F.R.C.S.,

Surgeon Emeritus (with beds) to the Cancer Hospital; Surgeon to the Gordon Hospital for Diseases of the Rectum, etc.

80 pp. and 33 plates. Bound cloth. Price 7s. 6d. net, post free 7s. 10d.

"It is the best exposition of the subject with which we are acquainted."
—*British Journal of Surgery.*

"Deserves to rank as a classic in the literature dealing with cancer of the rectum."
—*Bulletin of the Johns Hopkins Hospital.*

"Perhaps no surgeon of to-day has had a greater experience in treating cancer of the rectum."—*Surgery, Gynecology, and Obstetrics.*

BAILLIÈRE, TINDALL & COX

¶ The book has again been carefully revised. Every endeavour has been made to keep it abreast of approved modern theory and practice.

NOW READY. *SIXTH EDITION.*

MAY and WORTH'S
DISEASES OF THE EYE

¶ "'May & Worth' is recognized as one of the best o the text-books upon diseases of the eye intended for the use of students or practitioners. It is deservedly popular, for its teaching is clear, its mode of setting forth the various conditions is neither scrappy nor redundant, and—a very important fact—its diagrams are plentiful and illustrative . . . the book is well deserving of its acknowledged popularity."
—Edinburgh Medical Journal.

Demy 8vo. Pp. viii + 460, with 337 Illustrations, including 23 Coloured Plates. Price 15s. Postage 9d.

NOW READY. *Enlarged and Thoroughly Revised.* *FOURTH EDITION.*

JELLETT and MADILL'S
MANUAL OF MIDWIFERY

¶ "It is the most exhaustive treatise on midwifery produced in these islands."—*British Medical Journal.*
"This book is one to which the practitioner can turn with the certainty of finding practical advice for every obstetric difficulty."—*Edinburgh Medical Journal.*

Size 9½ × 5½. Pp. xii + 1,281, with 570 Illustrations. Price 25s. Postage 1s.; Abroad 2s.

NOW READY.

BESREDKA'S
IMMUNITY IN INFECTIOUS DISEASES

By A. BESREDKA, Professor at l'Institut Pasteur. Authorised translation by HERBERT CHILD, M.R.C.S.Eng., Late Hon. Surgeon, French Red Cross, Capt., R.A.M.C. (Ty).

¶ In this volume the author deals with the different aspects of the great problem which dominates all infectious diseases: that of vaccination, preventive as well as curative.

Size 8 × 5. Pp. vi + 320. Price 18s. Postage 6d.

JUST PUBLISHED.

MacLAREN'S
MEDICAL INSURANCE EXAMINATION:
Modern Methods and Rating of Lives.

¶ "An ideal text-book. . . . 'Excellent' is, indeed, the adjective which is properly applicable to it."
Medical Press and Circular.

This book contains the very latest data available, and covers its several field in a more complete manner than any of its work. It is therefore, a reference book of primary importance to all concerned with Medical Insurance.

SECOND EDITION. Greatly enlarged. Pp. xvi + 650. Price 30s. Postage 9d.; Abroad 1s. 4d.

THE FEMALE SEX HORMONE

By ROBERT T. FRANK, A.M., M.D., F.A.C.S., Gynecologist to Mount Sinai Hospital, New York.

¶ This work deals very thoroughly with the Biology, Pharmacology, and Chemistry of the subject, together with Clinical Investigations based upon the Female Sex Hormone Blood Test.

Size 6 × 9. xiv + 324 pp. 86 Illustrations. 33 Graphs. 523 References. Price 25s.

PSITTACOSIS IS INCLUDED IN THIS VOLUME.

DISEASES TRANSMITTED FROM ANIMALS TO MAN

By THOMAS G. HULL, Chief Bacteriologist, Illinois Department of Public Health. With an Introduction by V. A. MOORE, M.D., D.V.M., Director, New York State Veterinary College, Cornell University.

Size 6 × 8½. Pp. xxiv + 352, with 29 Illustrations. Price 25s. Postage 8d.; Abroad 10d.

The first appearance in English of a Famous French Classic

MAINE DE BIRAN'S
THE INFLUENCE of HABIT on the FACULTY of THINKING

Translated by MARGARET D. BOEHM, of th Johns Hopkins University. With an Introduction by GEORGE BOAS.

Size 6 × 9. Pp. 227. Price 22s. 6d. Postage 8d.; Abroad 10d.

7 & 8, Henrietta Street, Covent Garden, London, W.C.2

WITHOUT OFFENCE

Collection of Overdue Accounts

AN ACTUAL CONVERSATION

DOCTOR: "I have brought up some more accounts, Mr. Watson. I should prefer those marked with a cross to be collected in full. What I mean by that is, not by instalments."

MR. WATSON: "We should much prefer to collect them in the manner you suggest, Doctor."

DOCTOR: "Is that a natural statement, or a fact, Mr. Watson. I say this, because I frequently see varying commissions charged for various debts collected by instalments."

MR. WATSON: "It is a fact, Doctor. Collection by instalments alone does not pay. What makes this side of our work pay is the Annual Subscription and the Ten Per Cent. cases. The real point is, our methods produce good all-round results."

DOCTOR: "Agreed, Mr. Watson—go ahead."

For Hospitals, Institutions, and on Shipboard. . . . .

The
"METALIX-PORTABLE"
TROLLEY MODEL

THIS model is specially designed for use in hospitals, institutions, and on board ship. The trolley is mounted on rubber-tyred wheels and can be manipulated in confined spaces with the utmost ease.

In addition to carrying the apparatus itself, space is provided for all the necessary accessories—cassettes, etc.

Doctors throughout the world testify to the merits of the "Metalix-Portable." Have you given it your consideration?

AS an adjunct to the existing X-ray installation, the "Metalix-Portable" is invaluable—in Cottage Hospitals not already provided with an X-ray plant it is indispensable.

For the radiography of patients to whom a move would be undesirable or even dangerous. Use it too, in the X-ray room for all bone work requiring fine detail.

With the "Metalix-Portable" you can make radiographs of excellent definition. It is simple in use and there is nothing to get out of order.

There must be times when you feel the need for such an apparatus. Why not take the first step?—Write for full particulars now.

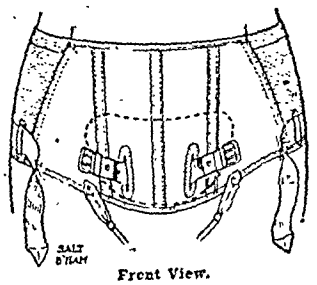
SURGICAL SERVICE
SALTAIR

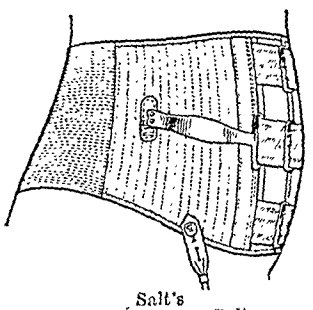
"SALTAIR SURGICAL SERVICE"

Comprehensiveness



of SALTAIR SURGICAL SERVICE is exemplified in the variety of types of appliances manufactured.

We have our own patents and registered patterns in practically every type of surgical appliance. We are constantly adding new types of supports and invite the Medical Profession to co-operate with us in experimenting with new designs, at our expense.



The Hall-mark of "Salt" distinction is the fact that every appliance is specially made for each individual requirement, as prescribed by the attendant practitioner.

Salt "comprehensiveness" embraces a service which has co-operated with the Medical Profession since 1793.

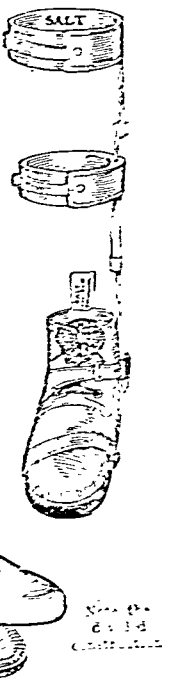
ARTIFICIAL LIMBS —

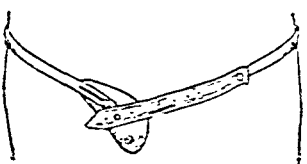
The Guarantee behind each Appliance made by Salts



Do you, as a Medical Man, realise the thoroughness of such a Guarantee?

It means that the appliance, specially built by us for your patient, will be altered, exchanged, or accepted back if unsuitable.

This is a safeguard to you and your patient, such as no firm of less reputation in medical circles dare provide.



Our long experience and practical knowledge enables us intelligently to interpret medical requirements with such accuracy that rarely are the terms of our Guarantee taken advantage of.

Intestinal Disinfection

ALLERGIC CONDITIONS & PROTEIN SENSITISATION

MUCH attention has of late been directed to states in which the subject has become sensitised to some substance, and on exposure to the same substance reacts in a characteristic manner.

The substances which may sensitise are very varied (e.g., animal dandruff and hairs, plant pollens and hairs, animal and vegetable proteins of foods, bacteria and their products) and the reaction may take the form of epileptic attacks, fainting fits, skin eruptions, asthma, etc.

In many instances the sensitisation is produced by bacteria or their products in the bowel, and by the exhibition of an efficient intestinal disinfectant the subject is cured. This has been found to occur in many cases of asthma, eczema and other skin diseases. The best of all intestinal disinfectants is Kerol, which acts as a specific cure in many of these cases.

For intestinal disinfection, use KEROL CAPSULES (keratin-coated); they contain 3 minims of Kerol. One to three capsules may be given three or four times a day after meals.

Please send for Literature and Samples, which will be sent free to any member of the Medical Profession.

THE NATURAL MINERAL WATERS OF

CARLSBAD

Sprudel, Muhlbrunnen, and Schlossbrunnen

These waters act:

(1) By immediate contact with the mucous membrane of the stomach and alimentary canal, allaying pains and spasms in these organs, and stimulating the digestive organs into activity.

(2) Through the blood. That is, they change its condition by increasing the proportion of alkali in the blood as well as in all derivative secretions (gall, urine, etc.).

Largely prescribed in cases of

Chronic Gastric Catarrh, Hyperaemia of the Liver, Diabetes, Gout, Gall-stones, Renal Calculi, Diseases of the Spleen, and of the Kidney and Urinary organs.

Bottled under Official Supervision at Carlsbad and regularly imported by the Sole Agents:

INGRAM & ROYLE, Ltd.,

BANGOR WHARF, 45, BELVEDERE ROAD, LONDON, S.E.1.

And at LIVERPOOL and BRISTOL.

Samples and Descriptive Pamphlet forwarded on application.

A MEDIUM FOR THE PEAT DISTILLATE PRINCIPLE

THE peat distillate principle has been put into harness, in the shape of sphagnum moss, by the surgeon. It has found its way in the shape of bog water, into the age old pharmacopœia of the Irish peasant. In both instances it has justified its use again and again.

The makers of Sphagnol preparations have devised a variety of convenient media for this principle, an ointment, soaps (Medical, Toilet, and Shaving), a lotion and suppositories. In each case the strength is from 5 to 15 per cent. and the medium of the highest quality. The preparations are on sale at all chemists at very reasonable prices.

Medical practitioners who would like to test the maker's claims will be supplied with generous free samples on application to Peat Products (Sphagnol) Ltd. (Dept. B22), 21, Bush Lane, London, E.C.4.

Invaluable as a Galactagogue

This nourishing and sustaining food drink is helpful to nursing or expectant mothers

NOT only hundreds, but literally thousands of cases are recorded in which this well-known preparation — Horlick's Malted Milk — has proved its efficiency as a body-building food.

It is particularly valuable as an addition to the diet of the expectant and nursing mother. For Horlick's is a perfectly balanced food containing fat, proteins and soluble carbohydrates combined together in correct nutritive ratio. It is prepared from fresh, full-cream cows' milk, selected wheat and malted barley — and, during manufacture, is partially predigested to ensure easy assimilation.

Horlick's is rich in valuable malt-sugars, but contains neither cane sugar nor free starch. It is therefore extremely easily digested, and highly productive of energy.

These characteristics make it valuable as a galactagogue. Its abundant nutriment supplements any deficiencies in the mother's regular diet, and promotes a regular and nourishing supply of milk, and its easy digestibility makes it acceptable when other forms of nourishment are unwelcome.

Taken during pregnancy, it builds up the mother and helps to maintain her vitality. A cupful taken regularly first thing in the morning frequently abolishes and almost invariably alleviates the discomfort of morning sickness.

Horlick's is now obtainable in two forms — the original, natural-flavoured Malted Milk, and the new Chocolate Flavoured form — identical in its constituents with the original Horlick's, but flavoured with fine chocolate. Horlick's is sold in sealed glass bottles, price 2/-, 3/6, 8/6, 15/-. Also in tablet form.

Further details may be obtained from Horlick's Malted Milk Co., Ltd., Slough, Bucks.

Have you a case like this . . . ?

WE quote below a testimonial we have just received, in the sincere hope that in reading an account of another doctor's problem it may help you solve your own.

6, Milton Street, Belfast.

"My son was at death's door suffering from ulcerated stomach . . . vomited everything. . . . He was wasted to a mere shadow. . . . Doctor advised Humanised Trufood . . . baby retained it and did not vomit one feed. Before taking Humanised Trufood baby was losing 6 to 8 ozs. every week. The first week after taking Humanised Trufood he gained 16 ozs., the second 18 ozs., the third 16 ozs., and has gained every week since. All his ills are gone, and we have not lost a minute's sleep with him since using your food. My friends say they cannot believe it is the same child. They were expecting to hear of his death any minute."

(Signed) PATRICK COCHRANE.

MEDICINAL GLUCOSE B.D.H.

Pure Dextrose.

The realisation of the fact that efficient carbohydrate metabolism plays an important part in the well-being of the individual has led to the recognition of Medicinal Glucose B.D.H. as a therapeutic agent of considerable significance in modern practice.

Glucose therapy is indicated in the nervous debility of children in asthma, prior to operation in order to prevent surgical shock, and for the various manifestations of carbohydrate starvation.

Medicinal Glucose B.D.H. is a crystalline powder unique in its degree of purity and unvarying in its therapeutic effect; indeed it is so pure that it is suitable for intravenous injection as well as for oral use. It is obtainable, in ½-lb. and 1-lb. tins, from all the principal pharmacists.

The Doctor orders *Thermogene*

BECAUSE:

(1) He knows it to be cleanly in use; whereas poultices and liniments soil clothes and skin, thus making examination with hand or stethoscope both unpleasant and difficult.

(2) He knows it to be fool-proof. It is always ready, and calls for no skill in preparation or application: It is never too hot, and cannot get cold and clammy. Scalding and chilling are alike impossible.

(3) He knows that in addition to—or because of—its definite therapeutic action in promoting surface circulation and in stimulating healthy metabolism it invariably comforts and soothes the patient, and eases his pain.

Thermogene is carefully prepared pure cotton wadding, remarkably soft and fleecy, freed from dust and other impurities, and impregnated with skin-stimulating vegetable essences.

A full-size box of Thermogene, with an interesting booklet on Surface Therapy, will be sent FREE to any medical man who is unfamiliar with Thermogene and its many uses in practice. The Thermogene Co., Ltd., Queen's Road, Haywards Heath, Sussex.

THERMOGENE

MEDICATED WADDING

THROUGH A CENTURY THEIR POWER TO STIMULATE AND RESTORE APPETITE, HAS MADE THEM THE CHOICE OF THE MEDICAL PROFESSION

BY APPOINTMENT

THE unique stimulating and restorative properties of Brand's Essence have been recognized by the medical profession now for nearly a century.

It was in 1832 that Mr. Brand in conjunction with a famous doctor discovered the process of conserving the pure juices of freshly killed meats in a convenient and hygienic form.

Since that time, Brand's Essences have been recommended regularly in serious illness and in convalescence. Their stimulating properties excite the gastric juices and rouse appetite. Delicious as well as easy to swallow, these Essences overcome the patients' reluctance to eat—prepare them for a more solid diet. They can be assimilated, too, without any strain on the digestive organs.

Brand's Essences are prepared under strictly hygienic conditions. To ensure purity, they are sterilized by heat processes under scientific supervision.

Brand's Essences (made from British Beef, Chicken and Mutton) can be obtained in small or large-sized glasses and tins at chemists throughout the world. Brand & Co. Ltd., Mayfair Works, South Lambeth Road, London, S.W.8.

A New Stride Forward in Nose and Throat Therapy

Mistol is a combination of eucalyptol, menthol and camphor in a specially prepared base of petrolatum. It is approved by leading nose and throat specialists for its quick action in relieving irritated and infected mucous membranes.
Due to its oily consistency, Mistol clings tenaciously to mucous membranes, keeping its soothing and astringent ingredients in direct contact with the inflamed parts for a considerable length of time.

THE FRENCH NATURAL MINERAL WATER

VICHY-CÉLESTINS

And the other State Springs of Vichy
(Property of the FRENCH STATE)

FERMENTATIVE DYSPEPSIA.

When the secretion is vitiated in quality, and the motricity of the stomach weakens, that organ dilates, and the gastric stagnation allows the micro-organisms of many ferments to develop. Quite a series of acids are then to be met with (butyric, lactic, acetic, etc.), which not only irritate the mucosa, but further, after their passage into the intestine, become absorbed by the lymphatics and swept into the circulation. Vichy-Célestins, by its slightly stimulating action, clears out the stomach, and this avoids stagnation and consequent fermentation. As, in addition to doing this, it modifies stomachal metabolism, the secretions return little by little to their normal physiological condition.

CAUTION.—Each bottle from the STATE SPRINGS bears a neck label with the word "VICHY-ETAT" and the name of the SOLE AGENTS:

RADIO-MALT

in all debilitated conditions

In northern latitudes the lack of sunshine and prevalence of colds and influenza during the winter exert inevitably a cumulative debilitating effect. By the middle of March reserves stored up during the previous summer are practically exhausted, and resistance against infection is lower at this than at any other time of the year; the manifestations of these conditions are familiar clinical pictures. The revitalising factor necessary to adjust the balance must serve the purpose not only of replenishing the reserve thus depleted, but also of clearing away from the system such after-effects of the winter season as catarrhal conditions, debility and general lack of tone.

Radio-Malt, by reason of its standardised content of Vitamins A and D and on account of the presence in it of controlled proportions of Vitamin B (B_1 and B_2), exerts a remarkable effect on the whole system; by assisting the better assimilation of food it creates appetite, prevents constipation and improves the body-tone.

Radio-Malt is unique, and there is no substitute for it.

LYSOL AND THE REASON WHY

The value of Carbolic Acid as an antiseptic has long been recognised, and it is used extensively by Hospitals and Nursing Homes.

Carbolic Acid, however, has certain disadvantages; and realising that considerable improvement was required, the originators of Lysol, after exhaustive bacteriological research, produced a more powerful but at the same time less toxic antiseptic for which they coined the name "Lysol."

Lysol as originally manufactured is more than two and a half times as strong as Carbolic Acid in bactericidal power, but in spite of this it is many times less toxic. Another advantage it possesses is that its soapy nature gives it an emollient action which is of great assistance in Obstetrical practice, Gynaecology, and similar purposes.

Because of these superior qualities, Lysol has become so widely recognised that it has very largely replaced Carbolic Acid as the standard antiseptic in the majority of Hospitals throughout the whole world. During the past forty years the original Lysol has been used and recommended increasingly by the Medical Profession, and it has never failed to give satisfaction.

In this country, however, the name "Lysol" became a generic term during the War, and, as a result, any antiseptic containing 50% Cresylic Acid may be termed lysol.

This has brought about an anomalous situation because many lysols of varying grades and qualities have appeared on the market; and to use inferior quality lysol is dangerous because it may not be constant in efficiency—it contains impurities which make it irritant—it is caustic in action due to the strongly alkaline soaps used. These detrimental qualities are not present in the original product.

The pure and reliable original Lysol is marketed under the name MARSHALL'S LYSOL by Lysol Limited, an associated company of Schulke & Mayr of Hamburg, who discovered the original product and who held the sole rights in the name "Lysol" up to 1914.

MARSHALL'S LYSOL is the only lysol made to the formula and specification of the originators, and the superior quality and efficiency of MARSHALL'S LYSOL remain unequalled by its numerous imitators.

Forty years of experience and bacteriological research go into every bottle of MARSHALL'S LYSOL, and the manufacturers know intimately the correct method for producing the most satisfactory product.

The quality of MARSHALL'S LYSOL never varies—it is a thoroughly reliable antiseptic, and when diluted as recommended it is absolutely harmless and non-caustic.

If you ask merely for lysol you may get an inferior product of uncertain quality; therefore, to ensure safety you should insist upon MARSHALL'S LYSOL and be certain that you get the genuine original product.

LYSOL LIMITED. LONDON, S.W. 20

IMPROVED FORMS OF THE HIGHLY ESTEEMED DIURETIN

Trade Mark **Calcium-Diuretin** Brand

Theobromine Calcium Salicylate.

Readily tolerated and devoid of alkaline taste. The chemical combination of the calcium component results in a valuable (complementary) augmentation of the Theobromine Salicylate action.

Trade Mark **Iod-Calcium-Diuretin** Brand

Iodo Theobromine Calcium Salicylate.

Most efficacious in stenocardial and asthmatic conditions.

Trade Mark **Rhodan-Calcium-Diuretin** Brand

Rhodan Theobromine Calcium Salicylate.

For the treatment of hypertonia. Most conspicuous improvement of the subjective high pressure symptoms.

Bottles of 25 tablets.
Hospital packages of 200 tablets.

PUERPERAL SEPTICAEMIA

It is now generally recognised, and has been again recently stressed by gynaecologists, that the principal causative agent in Puerperal Septicaemia is the Streptococcus Haemolyticus.

It is an interesting and important fact that Monsol, which is well known to have a selective action on Gram-positive organisms, has a particularly selective action on the strain Haemolyticus among the Streptococci.

The following table showing the relative dilutions at which Monsol is effective illustrates this.

STRAINS OF STREPTOCOCCI

DESIGNATION OF STRAIN	*SOURCE*	*DILUTION OF MONSOL*
"Diphtheritic"	Throat	1-100
Salivarius. Barnes 445	Mouth-Tonsillitis	1-100
Erysipelatis. 226	Lesion	1-150
Enterococcus Tissier 775	Faeces	1-150
Urine 8213	Urine	1-150
Rheumaticus. Beattie	Joint	1-300
Sputum A	Unresolved pneumonia	1-700
Sputum B	Unresolved pneumonia	1-700
Viridans 1080	Tonsil	1-1000
HAEMOLYTICUS 2060	—	*1-1500*
HAEMOLYTICUS B.C. 1498	—	*1-1500*
Mastitidis 2470	Mastitis	1-1500
Scarlatinae. Sherman 1892	Scarlet Fever	1-1500

The use of Monsol in obstetrics is, therefore, specially indicated owing to its selective germicidal power; while its non-irritant action on the most delicate mucous membranes and tissues, renders possible its use at dilutions far stronger than are germicidally necessary.

MONSOL PREPARATIONS INCLUDE:
MONSOL LIQUID, OINTMENT, INTERNAL CAPSULES, PASTILLES, DENTAL CREAM, TOILET SOAP, ETC.

NATURALLY RICH IN VITAMIN "D"

Smiler, fed on Cow & Gate

Dried Milk for Safety

At————deaths from diarrhoea and enteritis fell from 105 in 1923 to 67 in 1924, but rose to 109 in 1926. There was a fall in 1927 to 61, and a further fall in 1928 to 56. Professor ————M.O.H., writes: "Once more the relationship between these diseases and the sub-soil (four-foot) temperature, which used to be so constant, failed to re-appear. Among the most important factors in bringing about this amazing decline in mortality from these causes, I think we must place the wide substitution of dried milk for so-called fresh but highly contaminated milk————" Dr.————adds that until the methods of the farmers and others concerned in the milk industry have been revolutionised, and consumers have been provided with facilities for storage and education in the handling of milk, he is definitely of the opinion that liquid milk should be banished from the dietary of infants.

"Medical Officer,"
Jan. 4th, 1930.

This resumé shows clearly the advance made in medical opinion during the last few years. Figures such as these show conclusively that raw cows' milk—"Nature's food for the calf"—is unsafe and unsuitable for the human infant. Discrimination in the choice of a dried milk food is, however, essential.

The makers of Cow & Gate have for over a quarter of a century endeavoured by every means known to science to produce each year a better product, and in the light of this experience they postulate without fear of contradiction that there is a great gulf fixed between ordinary commercial dried milk and that specially prepared for infant feeding.

Some babies cannot digest full cream milk; they should be put on Cow & Gate Half Cream. (BLUE TIN)

HEWLETT'S
ORIGINAL PREPARATIONS.

HORMONIGEN
(HEWLETT'S)

Hormonigen Tablets (Hewlett's) contain the hormones of the thyroid, pituitary, ovary, and testes.

Useful in Neurasthenia and all asthenic conditions, obesity, chronic cardiac cases, aplasias of the pluriglandular system, and in anæmia. In Amenorrhœa, Dysmenorrhœa, and at the Menopause, Hormonigen is particularly effective, and even in chlorosis.

If there is high blood pressure, Hormonigen Sine Pituitary is indicated.

PRICE HORMONIGEN, OR HORMONIGEN SINE PITUITARY,

3/3 PER 100; 30/- PER 1,000.

UNG. IODERMIOL

An ointment of IODERMIOL that contains about 5 per cent. of Iodine, and is, therefore, stronger than the B.P. Ointment, whilst it does not harden or discolour the skin.

It has been found most useful for Enlarged Glands, Rheumatic and Gouty Affections, Lumbago, Sciatica, Swollen and Stiff Joints, Skin Diseases, Ringworm, etc. Ung. Iodermiol has also been used in cases of burns and scalds, and in the treatment of Chronic Lymphadenitis, Simple Bronchocele, and Atrophic Rhinitis, and in Purulent Ulcerative Otitis.

PRICE 6/- PER LB.

UNGUENTUM IODERMIOL et METHYL SALICYL. (HEWLETT'S)

Useful in the treatment of Enlarged Joints, Synovitis, Rheumatoid Affections, etc.

PRICE 7/6 PER LB.

LIN. BETULÆ CO.
(HEWLETT'S)

Therapeutically equivalent to several times its weight of Sodium Salicylate without causing headache, tinnitus, etc. Has proved most useful in the external treatment of pure Rheumatism, Sciatica, Lumbago, etc. The external dose is about one drachm rubbed over the affected parts.

In 5, 10, 22, 40, and 90-oz Bottles.

PRICE 10'6 PER LB.

VERONIGEN
(Formerly known as MIST. VERONAL CO.)
(HEWLETT'S)

A liquid Preparation of this prompt and reliable HYPNOTIC has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, and in ordinary cases of insomnia one fluid drachm of Veronigen (Hewlett's) is quite sufficient dose for an adult

Dose for Adults.—One fluid drachm diluted, about one hour before going to bed.

For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

VERONIGEN, 10 6 PER LB.

MIST. PRUNI VIRG. CONC.
(HEWLETT'S)

A valuable stimulant and expectorant cough mixture, containing Carbonate of Ammonium, Ipecacuanha, Senega, Squill, and Syrup of Wild Cherry Bark. Quite free from Morphine, Opium, or poisons, so can be safely administered to children.

Dose: 1 to 2 drachms diluted.

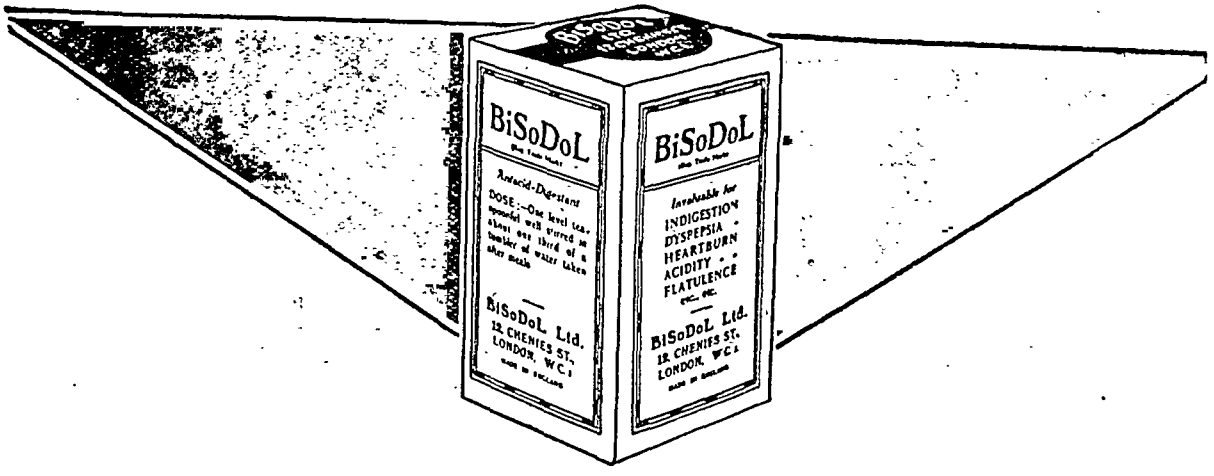
In 22, 40, and 90-oz. Bottles only.

PRICE 3'3 PER LB.

MIST. TUSSI RUB. CONC.
(HEWLETT'S)

A favourite and economical cough mixture, containing Hydrobromic Acid, Chloriodyne, Dilute Hydrocyanic Acid, etc. Most successful in allaying post-influenza coughs that are so persistent. One or two ounces diluted with water to make eight ounces forms one of the most effective and elegant mixtures that can be made, and certainly the least expensive.

In 22-oz., 40-oz., 4½-lb., and 8-lb. Bottles only



PRICE 2 9 PER LB.

Gastritis, Gastric and Duodenal Ulcer

That BiSoDoL is a therapeutically sound preparation will be readily appreciated from its formula.

BiSoDoL is a balanced combination of the Sodium and Magnesium bases with Bismuth Subnitrate, Carica Papaya, Malt Diastase, and Mentha Piperita.

BiSoDoL supplies a convenient and agreeable product for the treatment of gastro-intestinal conditions associated with hyperacidity. It is a valuable preparation for allaying such digestive symptoms as eructations, flatulence, distension and nausea.

BiSoDoL is also giving excellent results in the alkaline treatment of gastritis, and of gastric and duodenal ulcer as well as in the control of cyclic vomiting, and the morning sickness of pregnancy. In the latter the effect of BiSoDol has been especially noteworthy.

BiSoDoL

Samples will be gladly sent to Physicians on request.

BiSoDoL Limited,
12, Chenies Street, London, W.C. 1.

IZAL
IN MIDWIFERY

"Antiseptic precautions in Midwifery to be observed by Maternity Nurses and Midwives"

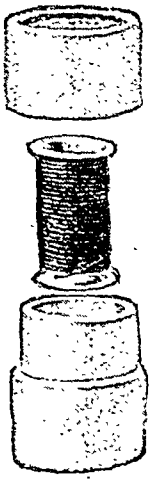
USING IZAL

Copies of these rules will be supplied free on application to NEWTON, CHAMBERS AND COMPANY, LTD., Thorncliffe, near Sheffield.

IZAL is not only one of the most powerful, safe germicides known to science, but it is Absolutely Reliable in all conditions of Use.

FOUR ADVANTAGES OF IZAL

1. Obtainable everywhere.
2. Only one standard strength.
3. The safest disinfectant for Midwifery Practice.
4. Does not roughen the hands.



Izal is manufactured by
NEWTON, CHAMBERS & CO., Ltd.,
Thorncliffe, Nr. Sheffield.

LONDON HOSPITAL 'CHORDA' CATGUT

Is prepared under and complies with

The Therapeutic Substances (Catgut) Regulations 1929 Licence No. 37

After extensive experimental work in the London Hospital, 'Chorda' Catgut has been evolved. This catgut is sterilized by a special iodine process which obviates the disadvantages hitherto associated with iodine sterilization.

'Chorda' Catgut is supplied on a glass reel in a specially sealed carton.

In boxes of 3 cartons
4/6 per box

In boxes of 12 cartons
16/- per box

All sizes 6/0 to 6 in plain or hardened catgut.

When ordering specify 'Chorda' catgut

Obtainable from

Allen & Hanburys Ltd., 48 Wigmore St., LONDON, W.1

and from all the leading Surgical Equipment Houses

"UMBROSE"

(Registered Trade Mark)

(Shadow Meal)

A Specially Prepared Barium Meal for X-Ray Diagnosis

These illustrations are reproductions of the actual work of an eminent London radiologist who employs "Umbrose" Shadow Meal as a matter of routine.

Fully descriptive literature on "Umbrose" will be gladly sent on request

The high degree of opacity of "Umbrose" ensures perfect shadow definition on the X-Ray plate. Other notable advantages of this meal are its freedom from toxicity, exceptional fineness, palatability, and the fact that it may be simply and quickly prepared in the X-ray room.

"Umbrose" (Shadow Meal) is prepared in three sizes as follows:

No. 1 contains 2 oz. $BaSO_4$
No. 2 „ 4 oz. „
No. 3 „ 6 oz. „

VITAMINS A, B & D
HAVE ALWAYS BEEN IN CADBURY'S MILK CHOCOLATE.

Fresh milk only is used in Cadbury's Milk Chocolate, which is made by a distinctive process incorporating the fresh milk direct with the chocolate.

By this process, the important Vitamins A, B and D, natural to fresh milk, are retained.

Owing to its concentrated form (there are 1½ glasses of milk in every ½-lb. cake) the chocolate is appreciably richer in Vitamin D than milk itself. Further, it contains the whole of the bone-forming calcium and phosphates present in the milk. All the essentials of an anti-rachitic food are contained in Cadbury's Milk Chocolate.

The dietetic value of milk has always been recognised by the medical profession—a convenient and concentrated form is Cadbury's Milk Chocolate.

This chocolate is sold in 2d. Bars, 6d. Packets, and 1/- ½-lb Blocks.

Reminders and Suggestions

SYRUP CREOSAL (DUBOIS)

A combination of Guaiacol, Calcium, and Phosphoric Acid (Calcium Monoguaiaco-Phosphate) pleasantly flavoured with Syrup of Orange Flower and Cherry Laurel.

An Excellent specific for COUGHS—whatever the origin—BRONCHITIS, LARYNGITIS, and all CATARRHAL CONDITIONS.

Bottles of 6 ozs.

SYRUP PERTUSSIS (GABAIL)

A co nbination of deodorised Valerianate, expectorants, and sedatives presented in a palatable form with Syrup of Raspberry.

An effective medicament for the PAROXYSMS OF WHOOPING-COUGH.

Bottles of 125 c.c.

Observations
ON
RESEARCH IN MEDICINE: ITS POSITION AND ITS NEEDS.*

BY
SIR THOMAS LEWIS, M.D., F.R.C.P., F.R.S.,
PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL.

WITH the greatest activity of medicine, that which ministers to the immediate needs of sick individuals, and which may be called *curative medicine*, we have here no direct concern. Our present interest is directed to that activity the immediate purpose of which is to advance knowledge; and this for convenience will be spoken of as *progressive medicine*. Progress in medicine can be followed historically along two main lines. The first is that traced from Hippocrates through Sydenham; it is the method of observation, and it has given us our descriptions of disease. The capacity of clinical observation to separate and define diseases was greatly enforced by the work of the famous morbid anatomists; the combined observations laid the foundations of modern clinical medicine. Laennec and Skoda, exponents of tested methods of physical examination: Bright, Hodgkin, Corrigan, Addison, who so ably identified and described individual diseases; these names but exemplify that most brilliant period of clinical activity, which was at its height in the earlier years of last century.

The second line of progress has been by the experimental method, using this word in its broadest sense; it is exemplified in the physiological field by the work of the physician Harvey and by Claude Bernard; in the bacteriological field by Pasteur and Koch.

While the methods of pure observation have long since passed their period of greatest activity, the experimental method continues to display amazing progress and growth. The experimental method in its development and in its deeper searchings has found the use of the lower animals increasingly necessary to its study of health and disease, and has led to the foundation of physiology and pathology as independent sciences, and to the great growth of modern laboratories; thus progress in medicine has come to be identified more and more with the work of these independent sciences and with the laboratories. Research, and especially experimental research—using the term experimental as it will be used throughout to designate experiment and not necessarily experiment on animals—tends to be delegated more and more to the laboratories, while clinical investigators have been brought by circumstances to become again content with observation, the ancient, traditional method of medicine. Cleavage along these lines is distinct and is deplorable, since it tends also to split off clinical medicine from invaluable contacts with physiology and pathology, and to render these last too exclusively intent upon their own spheres of work.

The final and practical aim of almost all medical science is to maintain health and to combat disease in mankind. It is in the very nature of things that the study of disease, to be effective, must begin as it must end, with disease itself, and that all knowledge applicable to human disease must owe its inspiration, directly or indirectly, to intimate contact with disease as this exists in living man. If the vitality of medicine is to be increased, it must be clearly recognized that there is a fertile science that deals primarily with patients, and this must be encouraged to a more vigorous growth. The science might be called "experimental medicine" if this term had not come to convey too strongly the idea of experiment on animals. It would be called clinical pathology, if the latter were not now fenced around by test tube and needle. It may be termed *clinical science*. This science seeks, by observation and otherwise, to define diseases as these occur in man; it attempts to understand these diseases and their many manifestations, and here especially makes frequent use of the experimental method. It makes definite experiments upon disease or watches the effects of experiment conducted by injuries, however these arise; it culls, or actually creates, and uses physiological and pathological knowledge immediately related and applicable to the diseases studied. Its value has been abundantly and frequently displayed in this country by such experimental clinicians as Ferrier, Horsley, Mackenzie, and Head. The very mention of these names is in effect a definition of the science that is in mind. Their work was not work that could be delegated to laboratories; it was inspired and sustained by direct contacts with disease; it was carried through in very large or chief measure by observations on sick people. The chief motive of the present paper is to inquire how this clinical science now stands. Admit that, like other sciences, it can be fostered; admit that, as with these, its development may not be left solely to sporadic enterprise, but can be hastened and guided by the creation of opportunity, and it is not hard to show that it now suffers from neglect.

We may begin to display this neglect by considering the present training and opportunities of the young worker, who, having completed his training in the preliminary sciences, aspires to clinical research. The first part of his course is set. He must become competent to manage sick people. In the past for two, in the future for three, valuable years—and while a contemporary student seeking a career in physiology is finally preparing for, or is actually engaged in, first researches—his attention is largely focused upon fitting himself to recognize a multitude of types of patients, and to tend their immediate needs. Qualification, at the least, is, and must continue to be, inevitable. Under our present-day system qualification is, however, but a preliminary: it is the later stages of preparation, through which the student must now pass inevitably, or almost inevitably, that require our very careful and serious consideration. The governing fact is that no student after qualification can expect to obtain control of clinical material, and at the same time to enjoy freedom to work upon it under adequate facilities, unless he enters upon and completes a well-defined career in a general teaching hospital. This career is of a conservative and most exacting type: it comprises not only house appointments with their valuable and early experiences of responsibility in handling disease, but a series of higher examinations, junior appointments, and heavy routine work, extending over years and arranged from one standpoint—namely, the training of a consulting physician. The man, ardent for research, who enters upon this course begins a long period of intense work, drawing him continually to its natural goal—consulting medicine: for his researches there is no certain prospect, and from this standpoint the ending is almost always barren. The reason is that preparation for success as a consultant and preparation truly suited to a career of clinical research present irreconcilable and deep-seated differences. Because the man who aspires to do research has at present no real option, but must pursue the first form of preparation, whether he desires ultimately to embark upon consulting work or not, it becomes imperative that we should examine this system and point out its defects in so far as it adversely affects a research career. And let it be said that on the matter of the suitability of our hospital system of training as a preparation for curative medicine no opinion is here offered other than to state that in many respects it is admirable for the purpose for which it has been devised: it is, however, a distinct question from the one now considered. The opinion that is put forward is that this system, and the atmosphere surrounding it, is but-

* For 25 years engaged almost wholly in research work upon problems arising directly or indirectly out of contact with patients; for many of the earlier years verging upon, or partly in, consulting practice, I have had what is perhaps a unique first-hand experience of the ways of medical research within the walls of a teaching hospital, from the time when there were no facilities or aids worth the name, to more recent times when these have come. Out of this experience, and out of an unusual association with younger workers, there should be something that can usefully be said to help those on their way. What is said is not put down hastily, but is the outcome of long years of experience, thought, and discussion; the views are in fact developed from those expressed (*Morning Post*, April 25th, 1914) by myself sixteen years ago.

I would be deeply concerned if anything written in this article should give rise to the impression that it has been inspired by any personal difficulties in obtaining facilities for work in the past, other than those difficulties that have been inherent in the situation; on the contrary, I recognize and gratefully acknowledge that my work in past years could never have been carried out without the abundant good will and help of my hospital colleagues.

ill suited to the advancement of medicine by research, and reasons for this view will be considered at some length.

An obvious defect in present training is the natural emphasis laid upon diagnosis. Diagnosis makes intense and incessant demands upon a man's time and energy over the early years of his studies. All who frequent the wards of general teaching hospitals realize how dominant is its note and recognize the constant urge of their surroundings towards it. Diagnostic knowledge and ability is the first essential of good practice; it therefore becomes in teaching hospitals the most direct and universal measure of medical learning; it is the stepping-stone to personal success. Its highly competitive character is mainly responsible for the atmosphere of intenseness in these institutions. It demands intimate and long experience of all kinds of diseases and of the manifold variations and incidents that each may display. But, from our present standpoint, it lends an exaggerated importance to knowledge of numerous rare diseases, of newly described phenomena of minor interest and of newly described methods and tests. A desire for encyclopaedic knowledge is fostered and grows; it moves in the direction of detail, for the phenomena studied are of great complexity and diversity, and present few of those connecting links in the form of principle or generalization that would serve to lighten what otherwise becomes a feat of giant memory. The result, and the quick result, of this system is the loss of much that is of value in the earlier training. By unavoidable neglect, the physics and the chemistry of the earlier student days pass into oblivion or become so rusty as to be of no more than occasional service. Even physiology, more recent in the recollection and offering easier points of contact, suffers very seriously; so that few can maintain more than a little part of their learning in it, and none can hope in these years to keep abreast of its continued advance. The physician at an early stage can and does throw much or all of this knowledge to the winds; there is knowledge of far more value to his daily work, and this he assiduously and rightly gathers in.

Again, in the attempt at clinical omniscience, learning drifts into superficialities and is not profound, for there is little time for critical weighing, for sorting, or comparison, and therefore there is little correlation of observation and simplification of ideas. Intensive clinical training, as this exists, leads in general to no real grasp of the problems set by disease or of means of solving them; it is too purely observational for this.

Between the method and outlook of curative medicine on the one hand and of progressive medicine on the other there are definite, inevitable, and sometimes profound divergencies. Consider diagnosis again. A diagnostician goes into his wards with one chief goal in view—it is to place a label correctly, to say that here is a species or a subspecies that someone has described, its name being this or that. It is legitimate to define diagnosis from our present standpoint as an attempt to recognize the known. That is an end-point.

When the clinical researcher goes to his wards his purpose is not to recognize the known, but to face the unknown. Diagnosis to him is but a starting-point, and when made it must be absolute. A diagnosis that is not reached without demonstrable security is unpermissible. Thus, while the interminable daily discussions as to what malady this or that patient suffers form a vital part of the consultant's training and of his work, they possess a very limited value to the research worker. And here it is to be repeated that he who would work with proper facilities in clinical research, works perforce at the present time in institutions in which, owing to its admittedly high practical value, diagnostic acumen is the password to the control of material.

A second divergence that it is important to recognize consists in the fact that curative medicine deals with the individual, while progressive medicine is collective in its outlook. The difference is largely controlled by the factor of time. If a man, by intent or otherwise, goes overboard, help comes, not from him who pauses to consider effects, but from him whose hand goes forth instantly to grasp and throw a rope. To the patient is distinctly and very properly the very centre point of consideration, but to progressive medicine he is but an incident. To the former the patient is a human being in trouble, and the object of knowledge possessed or sought is the mitigation of this trouble, the comfort and relief of the sick man. To the latter the patient is one who exhibits phenomena of disease, phenomena to be compared and correlated with those displayed by other subjects. Samaritanism, the greatest guiding force of medicine as a whole, is in practice an ever-present and direct, and in progressive medicine a much more distant, and therefore less obtrusive, motive.

When we consider these divergencies we realize that, while curative medicine is essentially observational, it constantly repeats itself; for that reason it is safe, for both the doctor and his patient; for the same reason it tends to be in large part sterile. Progressive medicine to be fertile must from the nature of things be experimental and original. And in this connexion we must note what will be obvious to thoughtful people—namely, that experimental research upon disease may very readily come into conflict with full solicitude for the sick. When such conflict threatens, as it not infrequently does, it is unquestionably right that research should give way unhesitatingly; any other system would be intolerable. Interference giving rise to temporary discomfort, the patient willingly co-operating, may be permissible; interference calculated to bring risk, however slight, to a patient's health must remain unjustifiable. This element of conflict is to be noted first, because it has to be safeguarded under any system of work. No worker can reasonably expect to be relieved of full responsibility in the care of any patient remaining in his charge; but, on the other hand, it is to be realized that no investigator can be successful who allows, or is forced by circumstances to allow, solicitude for his patients to preoccupy his mind.

The divergence between the individualistic and the collective method has been considered here from one relatively simple aspect—namely, from that of the different attitudes that may be adopted towards a patient within the ward of a hospital. It is perhaps almost unnecessary to point out that each method of thought has its practical applications to health, and that these applications, the one considering the health of the individual, the other of the community, often come into direct antagonism. This long-recognized antagonism will not be discussed further than to point out that it really constitutes but one of the issues in the general problem we are considering.

The third and chief divergence between curative and progressive medicine from our present standpoint is, however, intellectual.

In his daily work a practising physician has little or no control over the questions presented to his mind; mainly diagnostic, they are brought to him for solution one after another in great profusion. His solutions are reached in by far the greater number of instances by no process of logical reasoning, but upon the basis of previous experience or upon the basis of what we call intuition, a faculty often remarkably developed. Inevitably his mental activities are chiefly of this kind. The questions are not only profuse, but diverse; the mind is jerked forcibly from one question to another. When problems relating to the mechanism of disease present themselves, as they inevitably do to the more active minds and in the earlier years, then, before a clear line of thought can be established or followed to a satisfactory conclusion, the mind is torn from its problem to be confronted with others. The practice of medicine from its very nature is destructive to consecutive thought; its continued practice weakens the very habit to think consecutively, and therefore clearly, upon problems relating to the nature of disease, a matter very vital to progress. The atmosphere of the teaching wards is one with effort, mental and physical, but it is not an atmosphere of sustained argument. The problems faced by the investigator, properly circumstanced, are under his progressive control; they are never numerous and rarely disconnected; his observations are made without hurry, his thoughts are equally deliberate, and so his conclusions shape after long pondering, criticism, and revision.

The physician is forced by his daily work to ... frequently upon an insecure basis of fact and ...

In his work many of his decisions are frankly opportunist, many are wrong. But if most are right and many of the rest are harmless, then his work is a success, despite frequent mistakes. As a doctor he is sound, for his decisions, like the questions, are independent of one another. An investigator who draws false conclusions early in his research may see the whole structure of the work topple, for here conclusions follow in sequence and an early fallacy affects all; moreover, his work is placed on record and is submitted to close and critical supervision. To a physician, mistakes, if not too frequent, are of little consequence—they are indeed inevitable: they do not shake self-confidence as they do in the case of the research worker. Self-confidence is by general consent one of the essentials to the practice of medicine, for it breeds confidence, faith, and hope. Diffidence, by equally general consent, is an essential quality in investigation, for it breeds inquiry. Here, then, are chief characteristics, each necessary in its own sphere, each unsuited to the other. The two irreconcilables do not stand alone, but find natural companions. A natural companion of confidence is an easy and uncritical acceptance of statements of fact and of hypothesis; it is often coupled with a very wide and diverse acquaintanceship with other men's work and thoughts. The companion of diffidence is scepticism; it tends to be coupled with knowledge less extensive, but derived more from personal experience and analysis, knowledge more precise, and often more fundamental. The very essence of daily observation and thought in scientific work is the continual effort to discriminate as closely as possible between what is true and what is less true or actually false. The standard of truth attained by constant and deliberate cultivation among scientific men in their work greatly transcends that in any other sphere of human thought. It is the standard that allows no statement to pass without full qualification, without full display of its limitations. It is a standard essential to progressive work, but one highly inconvenient, and even obstructive, in the practice of everyday life. The mind of the craftsman dwells on what he knows, and he delights to use and to display this knowledge. The investigator's mind dwells in the main on the unknown and puzzling, and his eagerness is often towards displaying doubts and difficulties. The adoption of a laboratory diffidence by a practitioner would soon ruin his practice. The acceptance of the easy standard of conclusion found in practice would similarly end a research worker's usefulness.

The divergencies between practical and scientific medicine, and especially between their manner of thought and standard of accuracy, are in actual fact profound and far-reaching. They are perhaps as profound as, they are certainly not dissimilar to, those exhibited in the past between orthodox religion and science.

Preliminary consideration has now been given to the training available for the man who desires to devote himself to clinical science. It is a training developed to suit the consultant practitioner rather than the research worker. It has also been shown at length how widely the methods of work and of thought in these two spheres differ. It is the methods of curative medicine that dominate in general hospitals, and it is in this atmosphere that the bulk of investigational work upon patients is now done. Many, if not most, of the difficulties that at present face the clinical investigator arise out of the past and present control, be it direct or indirect, exercised by curative medicine over the facilities for such work and its recording. This control, absolute a few years ago, still predominant to-day, was quite natural, and indeed strikingly beneficial, in its period. If we omit consideration of quite recent times, it is true to say that investigational work in clinical medicine has been undertaken almost exclusively by, or at the exclusive encouragement of, men earning their livelihood in practice, and that practically the whole of our familiarity with the forms of disease as these are found in living human beings, and with the spontaneous manifestations of these diseases, is due to the efforts of such workers. This indispensable knowledge has been gained by the method which in the beginning of all biological science is fertile—namely, by observation of spontaneous phenomena, the method from the earliest times most natural to, and assiduously cultivated by, physicians. Eventually, however, the fertility of this method greatly declines by a process of exhaustion, and, for those who can read the signs, this time has come in medicine.

There are, no doubt, many important forms of disease yet to recognize, important and spontaneous manifestations yet to note; but the experience of the last few decades has shown this type of work to be decreasing in fertility, while its place is being filled by other and more successful methods of exploration. It is also evident that the continued separation of disease into types can be pressed too far, and that a subdivision which may perhaps have some immediate practical use can help to conceal underlying mechanisms held in common, and thus to hinder progress in studying the nature of disease. It is abundantly clear that present progress in clinical medicine is less and less due to observing what chances to happen in beds filled by the routine demands of unselected sick people and of teaching, and more and more attributable to intensive study of selected cases in which manifestations are deliberately sought or actually provoked, or upon which new and often highly technical methods are employed, which are derived from prolonged and searching studies in laboratories. It is equally clear that successful research work in medicine is becoming more and more difficult for the man engaged in practice to prosecute; it is becoming more and more the province of men who train themselves in technical methods of work and in suitable habits of thought.

It is far from my intention to imply that work of a progressive kind cannot be carried out exceptionally by men engaged in practice; on the contrary, there are some directions—for instance, prognosis—in which investigations can rarely be pursued with equal prospects of success by any other group of workers. There *is* the intention to imply that in general neither the training nor the daily routine of practice conduces to the type of investigational work which progress in medicine now chiefly demands; and that the practice of general medicine by continually acceding to opportunist and hurried conclusions definitely tends to unfit a man for research. Conversely, the prosecution of research in medicine tends in general to unfit for practice; and the more whole-heartedly and continuously research is undertaken, and the deeper the research goes, the less fitted the worker becomes for the care of unselected patients. This is clearly recognized by workers themselves, and, as long as there is no reasonable prospect of careers in research, will continue to discourage them from developing full research efficiency. It is in part for this reason that research in medicine is most compatible with specialism; the opportunity to undertake progressive work is in fact often the main justification for specialism. It is not possible in research to maintain full familiarity with general medicine, with its ever-changing devices and palliatives, when so much of both time and energy are concerned in studying matters that have no immediate relevancy to practice, and in laboriously and accurately collecting data and critically forming conclusions. The idea, more prevalent perhaps in certain foreign countries than in our own, that research is a suitable introduction to general consulting practice, is not only intrinsically unsound, but has proved itself mischievous. After his qualification a man, by attempting investigational work for a short space, and thus familiarizing himself with methods and especially with the difficulties of gaining new knowledge, will often broaden his views and increase his capacity as a teacher. Ability to undertake research, however, apart from its providing a possible gauge of intelligence, is no criterion of practical capacity; and experience in research, especially on the laboratory side, has little or no value in practice; consequently, when preliminary years are spent in large part in this way, they displace years of more valuable practical experience. The proper sequel to such research is not practice but further research—in short, a career largely concerned with investigation.

The serious aspect of the wide-spread encouragement of transient research is that, while such work rarely possesses scientific value, yet the reporting of it has acquired a recognized commercial value, and its realization in the

latter way becomes much more often than not the real goal in view. The goal referred to is in certain circumstances a perfectly legitimate one. It is a most desirable and healthy thing that good teachers should use the medical press to inform; it is right that contacts between consultants and general practitioners should become established by this means, and that through periodicals new work of established value should be brought to the knowledge of the profession as a whole. But the present system is obviously capable of, and is actually subject to, grave and frequent abuse; the abuse consists in the redundant publication of articles intended to pass muster as records of serious original research. Now the editors of the journals concerned are for the most part either whole-time editors or are actually engaged in practice. In neither case are they trained by long practical experience of research to deal with such articles critically or to judge them well; their daily contacts are with curative rather than with scientific medicine. Thus it comes about that there is little or no attempt on the part of editors collectively to stem the tide of pseudo-scientific publication; its amount is controlled almost exclusively by the desires of writers, and the tables of our libraries groan under an ever-increasing weight of periodicals. Research is widely exploited for professional ends; records of imperfect and actually unsound work find an almost open path to the printing press; reports of purely repetitive work have reached an extraordinary and most undesirable magnitude; many papers are republished almost in duplicate. The effect of such publication has passed beyond the bounds of menace; it has grown to form a distinct barrier to progress, with which more serious workers recognize they have to contend. The baneful effects are twofold. By its mass it conceals work that has value; by its quality it undermines the general standard of accuracy in observation and thought. Current teaching in the wards and textbooks, current methods of thought in practical daily work, are built in very large part upon the basis of published articles, past and present. The quality of such articles is a matter of vital concern to professional work, both directly and also indirectly, through its influence on progress.

Main functions of workers in progressive medicine are to consolidate old and to explore new ground, to watch the general tendencies of teaching, and to bring the results of their work within the reach of practitioners and thus to practical application. From several of these standpoints there is, in considering the present position of medical research, something more to be said.

In research, one step forward leads to another; researches begin from an accepted foundation and proceed. It behoves the worker to examine closely the foundation from which he starts and to make sure that this ground is solid. In research that directly concerns patients this preliminary work of consolidation is particularly arduous. A physiological worker can in very large measure start from the records left by previous workers; in medicine, as things now stand, this procedure is less safe. The relative unreliability of clinical statement of fact, and especially of conclusion, comes from several sources. Clinicians who record facts and views are not chosen, as for the most part are physiologists, for their ability to use precise methods of observation and of thought; in medicine inaccuracies in statement of fact are, owing to the material used, more difficult to detect, penalties for mistakes are less severe; the standard of truthfulness, in the sense previously indicated, is far less rigid, than is the case in physiology. A very grave defect in medical publication, from the standpoint of progress, is the dearth of systematic statements of evidence. In a very large proportion of instances, satisfactory and recorded evidence for current clinical beliefs is either most difficult to discover or is non-existent. Far too much stress is laid upon suggestion; far too little upon the proof. In this relation it is sufficient to mention therapeutics, but the defect is not confined to this branch.

There is a great work to do in close and critical revision of present beliefs in every branch of clinical medicine. Upon the extent and thoroughness of such consolidation the future rate of progress will in large part depend, as it has depended *in no small* measure in the case of cardio-vascular knowledge in the past few decades.

It is essential to concerted progress that there should be more exact definition of terms applied to disease and its manifestations, for close definition would bring increased clarity and would diminish the prevailing confusion of tongues. It is essential to progress that closer attention and study should be given to the precise laws relating to cause and effect; that they are widely misunderstood is illustrated sufficiently by a common tendency to enumerate under "etiological" headlines many and diverse causes of a single effect. It is essential to progress that observational work should be far more widely supplemented by the experimental method and by its manner of thought, and particularly that a full understanding and rigid use of controls and comparisons should develop extensively. Finally, it is essential to draw more closely together the bonds between physiology and pathology on the one hand, and clinical medicine on the other.

These activities, these reforms, have become beyond the power of curative medicine; they can be properly encompassed only by men who are not beset by numerous and diverse daily tasks, who have ample leisure for study and for reflection, who in training have acquired special and suitable experiences and have deliberately cultivated those habits of mind that conduce to successful investigation, who, in brief, make research a life work.

REMEDIES.

The present weaknesses of medicine, regarded from the standpoint of its progress, have been discussed from those points of view that suggest remedies.

The great contribution of curative medicine to knowledge of disease as displayed by mankind has been emphasized. Curative medicine has done more than that. The allied sciences physiology and pathology are its direct offspring, and have ultimately drawn their chief inspiration from it. Not many decades have passed since it became recognized that physiology must assume its own control; within a brief period its progress as a science became remarkable. Pathology has become more recently, though less completely, free, and is making not dissimilar history. These associated sciences are rapidly outstripping clinical medicine in new developments. The fault must be assigned to medicine, which, failing to pull its weight and keep abreast of the rest, threatens to disrupt the team. It is for clinical medicine, the most dependent but the most important of the group, to maintain contact and to draw renewed strength from its more vigorous progeny, and not, as now, to lag preoccupied. The remedy lies in the emancipation of clinical science from the controlling influences and demands of routine practice; for therein lies its chief weakness. Just as it became necessary to the full development of physiology, so it has become necessary to that of progress in clinical science, that its workers should enjoy independence.

The first step to be taken is the training of a group of workers with a view to their devoting their lives primarily to research, making disease as this occurs in man the centre point of their studies. The essence of the worker's training in all the concrete sciences consists in the development of correct methods of work and thought; accuracy in observation and in measurement; in biological science especially, a full understanding of the experimental method; a firm grasp of the nature and use of evidence; to know how to test and how to weigh, to know how to sift out error, to be able to judge the truth or falsity of statements. From the time of qualification the worker we are considering should enjoy full freedom to develop along these broad and recognized lines; he should have the opportunity to acquire such technical methods as may be needed in the pursuit of given problems, and freedom from the recurring fear of failure as an expert and practising diagnostician. He should have ample leisure to maintain close contacts with physiology; for, if he become a successful worker, he will not only put physiology to practical use, but, like his predecessors from Harvey's time down, will help the growth of physiology, and will stimulate progress in directions in which from time to time it will respond to stimulation—namely, into the more biological channels.

A simultaneous step must be the assurance that careers will be provided for those who train themselves successfully. And careers must be assured to individual workers at the earliest possible moment. Young and competent men cannot be expected to hazard the best years of their lives in long and special training without reasonable prospect of corresponding careers before them.

There are at present a very few academic posts, the units, concerned primarily with organized teaching in the schools, appointments of uncertain development and destiny, but offering, it is true, limited possibilities of research. Sure it is that as long as these posts are concerned with the function, important as it is, of teaching general medicine, their capacity to advance medicine by research will remain limited. There are also one or two purely research posts with full facilities; but these are personal appointments, and, being such, cannot be regarded as possessing stability.

It is unreasonable to expect, it would be unwise to advocate, the sudden creation of many posts; for there are not the adequately trained men to fill them. But the vicious circle now existing, whereby there can be no posts till there are trained men, and no trained men till they can see the prospect of posts, must be broken. It can be broken by clear statements of policy that posts will be made for those who render themselves competent for such careers. The posts must be full-time posts, for full-time work can alone ensure the leisure for efficient study, and freedom from that most distracting of thoughts, the imminence of an alternative career. The workers must be secured free and full access to the material they desire to study, and *full medical charge of that material*: work upon patients in another's charge fails to give sufficient freedom of control and dulls the fine edge of personal responsibility. General hospitals provide the necessary wealth and diversity of material; a teaching element in general hospitals sorts the material and renders it quickly available. The presence of research departments in general teaching hospitals stimulates teaching, and links science and art. For these and other reasons these hospitals are very probably the most suited to house such departments; but if that is the decision these departments should enjoy independence of the more purely curative departments, they must in no sense be subordinated to these, as is the strong and natural present tendency. The need is for *research physicians*, and their departments should include adequate but not abundant beds, and proper laboratory facilities; there should be arrangements for exchange of patients with other departments of the same institution, ensuring by this means supply of material and relief from the care of patients no longer suited to research. Their teaching should be limited to the demonstration of new methods and observations, and to the exposition of new ideas.

The future creation of research posts requires the present promise of financial backing; their creation in teaching institutes would require the early promise of active co-operation by these institutes; the alternative is the foundation of special hospitals or institutes.

The future of medicine lies with the younger and recently qualified generation and with their successors. It is within their power to bring clinical science in this country to a great revival. It is for them to bind themselves into a new association, which by influence and by example may carry the standard of observation and thought to precisely the same level as prevails in allied sciences, and firmly to link up with these on the one hand and with practical medicine on the other. To this end existing associations of physiologists and pathologists will not suffice them. There are problems arising out of contact with patients that are of little or no interest to the associated sciences. It is necessary that clinical science should enjoy its own intimate and untrammelled discussions. It is necessary that it should constitute its own courts of inquiry, of criticism, and of approbation. It is necessary to its full development that it should have its separate scientific societies, should control its own publications, and should be able to confine its original reports to journals restricting themselves exclusively to original matter of proper quality. It should develop its own training ground for new recruits. It should achieve independence and freedom.

EIGHT HUNDRED CONSECUTIVE OPERATIONS FOR APPENDICITIS.

BY

STANLEY RAW, M.D., B.S.DUNELM., F.R.C.S.ED.,

SURGEON, SUNDERLAND ROYAL INFIRMARY: VISITING SURGEON, HIGHFIELD HOSPITAL.

On returning from France in 1919 I decided to take careful note of all cases of appendicitis that I operated upon, first with a view to more firmly establishing, modifying, or altogether disestablishing the very definite ideas that I held upon the treatment of the disease; and, secondly, in the hope of being of some assistance in the diagnosis of its atypical forms; but I determined to publish no results until the number of cases exceeded 500. When this total was reached I decided to go on over a ten years period. This produced 782 cases, and another month completed the 800. The period covered is from January, 1919, to February, 1929. The total does not include the very many cases in which I have removed the appendix as an adjunct to operations upon the bile passages, stomach, or duodenum, nor those in which I have removed a diseased appendix when I came across it while I was operating in the peritoneal cavity for some other purpose. It is strictly limited to operations performed for appendicitis *per se*, or its results, and it includes all of those cases. An additional point of interest is the fact that in December, 1921, I made a radical change in my operative technique—a change suggested to me by Mr. Upcott of Hull—and its results have been so good that it is now my universal practice.

A glance at my tables will show that 462 cases (that is, 57 per cent. of the whole number) were either interval cases—that is, cases that had weathered at least one acute attack—or they were acute cases that had gone on to perforation. This is a very undesirable state of affairs, and it is especially undesirable when we consider that, apart altogether from the risks of the severe, and possibly fatal, complications that may develop during the course of palliative treatment, early operation offers the quickest and least painful method of recovery from the initial attack, with, of course, the additional advantage that this recovery is final.

In my opinion there are four principal reasons why early operation is not the universal practice.

1. The first, and, as I think, now the commonest, is the fact that patients do not summon the doctor soon enough.
2. The second is the fact that textbook descriptions are frequently misleading, in that the symptoms there described are in reality late symptoms, and consequently practitioners may be tempted to await their appearance before calling in surgical aid.
3. The third is that symptoms are frequently atypical, because the appendix is by no means always in the normal anatomical position.
4. It is extensively held, and, I regret to say, taught, that operation is unnecessary until palliative measures have failed; and that it is inadvisable after the second day of the attack.

My object is to combat these reasons. The first can only be combated by the education of the people, and more particularly by educating them to avoid aperients for abdominal pain. Abdominal pain means that some intraperitoneal structure is inflamed, distended, perforated, or obstructed, and the giving of an aperient in such circumstances is about as sensible as would be the waggling about of a septic finger. I am convinced that castor oil is responsible for more perforated appendices than is any other single thing or act. For the second reason the makers of books must be held responsible, and I hope they will mend their ways; while the third can only be combated by our own experience and acumen, and the fourth will disappear when those of us who are opposed to its teaching are able to convince its holders that better results are to be obtained by its abandonment.

Acute appendicitis is still the commonest of all acute abdominal emergencies, and while it is met with in patients of all ages, by far the greater number of cases occur between the ages of 12 and 25, and consequently the majority of patients are otherwise healthy and vigorous

young people. The attack commences suddenly, and the first symptom is pain, usually referred to the umbilicus. Shortly after the onset of the pain nausea or vomiting supervenes, to be quickly followed by tenderness over the right iliac fossa. These symptoms—pain, vomiting or nausea, local tenderness, and in that order—are the classical symptoms of appendicitis, and upon them alone one would be justified in making a diagnosis. Fever, leucocytosis, increased pulse rate, local swelling, dry furred tongue, peritonitic facies, etc., are undoubtedly symptoms of appendicitis, but they are late symptoms, which in an ideal world would never be encountered, and their presence means that someone has been responsible for inadvisable delay.

If, therefore, we see a patient who exhibits the above three symptoms—pain, vomiting, and local tenderness in the right iliac fossa (which I repeat because of the enormous importance of the sequence)—our first suspicion must be that he is suffering from appendicitis. Up to this point we are, of course, only suspicious; we must be reasonably certain before we can recommend a patient to submit to operation. The scope of this article does not permit of an exhaustive examination of the differential diagnosis of appendicitis from other diseases. It must suffice to say that before a positive diagnosis of appendicitis is made the possibilities of the case being one of pneumonia, diaphragmatic pleurisy, renal or ureteral calculus, or infection, intestinal obstruction, biliary colic, gastric or duodenal ulcer, acute pancreatitis, intussusception, tuberculosis, carcinoma, salpingitis, ruptured ectopic gestation, cyclic vomiting, pneumococcic peritonitis, Henoch's purpura, hip disease, a gastric crisis of tabes, etc., must be weighed; as also must it be decided whether the patient has a definite abdominal lesion of surgical consequence, or is merely suffering from an unimportant temporary disturbance, such as a bilious attack in a child, or a transient colic in an older patient; and the only warning that I would issue in this connexion is that it should always be remembered that a patient who has had many trivial attacks of colic or biliousness, or whatever it has been called, may on this occasion have a really important lesion.

If after a careful review of the case the diagnosis is still in doubt I advise the following course in all cases of acute abdominal emergency. Keep the patient in bed, and apply a warm fomentation over the painful and tender area. Starve him—absolutely. He must not even have a drink of water by the mouth, and, of course, he must have no opiate. The whole immediate object is to allow an inflamed structure to quieten down, extravasated products to become localized, or an obstructive viscus to become released; and this can best be done by the abolition of peristalsis. Having ordered this treatment, see the patient again in two or three hours. By this time the diagnosis will have become reasonably certain, or, if not now certain, the time has arrived for the assistance of a colleague with the case. Assuming that the diagnosis of acute appendicitis is now established, I am definitely of the opinion that, save in the circumstances mentioned below, immediate operation should be advised.

There is one great pitfall to avoid during this preliminary stage: beware of the sudden apparent improvement. Most practitioners have already had, and all in the course of time will have, experience of the following case.

He is called to see an acute abdomen, and, suspecting an attack of appendicitis, he orders palliative treatment. At a subsequent visit he is received with joyful smiles, and is told that the patient is so much better. The pain suddenly ceased, and all is well. All may be well; but, if the attack was really acute, it is more likely that a tragedy is in progress, and that the sudden relief from pain was due to the appendix rupturing, with a consequent release of the pressure upon its distended walls. Before joining in the general rejoicing the doctor should examine the patient carefully, and if he finds that the relief from pain has been followed by an increased pulse rate, a rising temperature, an increased area of local tenderness, a grey and anxious facial expression, and other signs of peritoneal infection, he can be sure that, far from all being well, all is very ill indeed, and instant operation has become imperative.

In order to get that operation carried out all our tact and firmness may have to be brought to bear, for we must remember these two things: (1) Pain is the only thing that really concerns a patient who is acutely ill. (2) It is very difficult to persuade him that he is not better when his pain has markedly diminished in severity. Finally, we should remember that in the early stages of the attack the severity of the vomiting is usually directly proportional to the degree of distension of the appendix, and therefore the more severe the retching the more likely is the appendix to perforate early; also, we must remember that, as a general rule, those attacks which commence by waking the patient out of his sleep are going to be severe, and they brook no delay.

I have rapidly passed over the symptoms of appendicitis in its diagnosis from other conditions, first because these things are too well known to need a lengthy recapitulation here, and secondly, because I want to devote some space to the consideration of the most difficult element in differential diagnosis. This is the apparently paradoxical diagnosis of appendicitis from itself. I stated as my third reason why early operation is not universal, "the symptoms are frequently atypical, because the appendix is by no means always in the normal anatomical position." This fact presents the greatest problem in the whole question. The symptoms already described are those of an attack in the normally situated appendix. Normally the appendix is lying behind the ileo-caecal junction, with its tip directed towards the spleen. My own experience of the inflamed appendix is that it is not often in this situation, and quite possibly that is why it becomes inflamed. Where may it be?

For practical purposes of diagnosis it should be realized that the appendix may be internal to, external to, behind, or below the caecum. When it is internal to the caecum it is probably lying in the normal direction, but its tip may be in front of or behind the mesentery, and upon this distinction will the local signs vary. If it is in front of the mesentery there will be early and considerable local tenderness and rigidity, and the diagnosis should present no difficulty; but if it is behind the mesentery these local signs will be less well marked because of the intervening coils of small intestine, and the consequent freedom from irritation of the parietal peritoneum.

When the inflamed appendix is external to the caecum it may be in the iliac fossa pointing upwards, lying between the caecum and ascending colon internally and the parietal peritoneum externally. In either of these sites the parietal peritoneum will be irritated at an early stage of the attack, so that tenderness and rigidity will be well marked, and should not be mistaken.

When the appendix is behind the caecum the symptoms may be very slight, and their meaning obscure. Usually pain is less, and it may be altogether local, while tenderness over the appendix is often very slight, as very little, and sometimes no, parietal peritoneum is involved. Vomiting and nausea may be absent, as also may local rigidity. A very valuable sign which is nearly always present in these cases is the local tenderness which can be elicited by pressure in the flank below the right costal margin at the outer border of the erector spinae; though it must be remembered that this is a common situation for tenderness in the prevalent sufferer from chronic rheumatism.

When the appendix is below the caecum its distal end is frequently hanging over the brim of the true pelvis, and it is in this event that the greatest difficulty in diagnosis arises—largely because the inflamed appendix is for the time being entirely a pelvic organ. There is no local tenderness or rigidity of the anterior abdominal wall, and, furthermore, the inflamed tip may be lying upon the bladder or rectum, causing painful micturition or tenesmus; or it may, by irritation of the peritoneum over the obturator foramen, give rise to symptoms suggesting an inflammatory condition of the right hip-joint; or by attachment to the Fallopian tube make the diagnosis between appendicitis and acute salpingitis almost impossible. Before the pelvic appendix perforates epigastric pain and vomiting will be the most marked symptoms, and may lead to a suspicion of a lesion of the upper abdomen; while after perforation the true state of affairs may be in doubt until a rising tide of dullness appears above the inguinal ligament giving us the unwelcome information that the pelvis is full of pus. It is this type of attack that is urgently in need for a rectal examination. Rectal examination should, of

course, be made in all cases of abdominal illness, but in the ordinary course of events its omission is an easily condoned sin, for there are few things that patients object to so much, and more especially do they object to such examinations in children. If, however, there is one class of case more than another in which a rectal examination is imperative it is in the case of the suspected pelvic appendix.

Finally, as to the situation of the appendix. It must be borne in mind that in a small proportion of cases the caecum has not descended into the right iliac fossa, and therefore the appendix may be found anywhere between the liver and its normal site, while in a patient with a very movable caecum it can wander into an inguinal hernia sac or other unusual situation.

Before discussing treatment I should like to say a word or two about the probable results of rupture of the appendix in these various situations. In the case of the internal or pelvic appendix they are likely to be hazardous or tragic. If the internal appendix is lying in front of the mesentery its rupture places the patient in imminent danger of extensive flooding of the coils of small intestine, and a consequent and rapid general peritonitis; therefore this type is by far the most dangerous to leave. If the appendix is behind the mesentery there is more chance of the formation of a limited, local abscess, but a very real risk of the onset of acute intestinal obstruction due to the involvement of the ileo-caecal region in the inflammatory products. Delay with the external appendix will, on the other hand, probably result in nothing more serious than a well shut off local abscess (though this is surely serious enough); while in the case of the retrocaecal appendix we have the additional risk of portal infection, subphrenic abscess, etc. Delay with the perforated pelvic appendix will certainly lead to serious trouble; at the best a local abscess or a collection of free pus in the pelvis with all the dangers of septic absorption, and a weary and prolonged convalescence, followed by the lifelong risks and discomforts incidental to a pelvis full of adhesions; at the worst a catastrophe; and it is the pelvic appendix that is most frequently overlooked, because its symptoms show the greatest departure from the usual textbook description.

TREATMENT OF ACUTE APPENDICITIS.

In considering the treatment he should recommend for acute appendicitis the uppermost thought in a doctor's mind should be that appendicitis is an acute inflammatory infection of an intraperitoneal structure that may lead to the death of his patient. The second thought should be that it is quite impossible for him, or for anyone else, to know the actual state of the particular appendix under review without seeing it. If he accepts these thoughts the only conclusion that he can come to is that immediate operation is the proper, as it is the safest, treatment.

That this view, in early stages of the attack, is becoming fairly generally recognized is a matter to be thankful for, but unfortunately it is still extensively held that immediate operation should not be advised if the patient is not seen, or the disease not recognized, until the second, or later, day of the attack. I entirely dissent from this view, and, excepting as mentioned below, I advise operation as soon as possible after diagnosis, irrespective of the stage and duration of the attack. I absolutely refuse to trust the appendix, and my experience of my own and others' work convinces me that the advocates of the alternative policy greatly exaggerate the risks of operation during the later days of an acute attack. That there were grave risks in the pre-aseptic days I readily admit, but these risks disappeared with the abandonment of the use of strong antiseptic lotions, the introduction of the practice of surgeons wearing sterile gloves and masks (by far the *greatest* surgical advance in my own time), the better understanding of the functions of the peritoneum, and the *improved* technique in the toilet of the wound. I must leave my results to prove the truth or otherwise of *my contention*. Most of my own acute cases were operated upon on the second or a later day. In none did I regret *my decision* to operate; in many of them I was supremely thankful for the views I hold.

The only occasions upon which I would advise delay, or an alternative treatment, are when:

1. The attack has practically subsided before the patient is first seen.
2. The patient is unable, because of some intercurrent disability, to stand an operation.
3. Operation is refused.

If the attack has practically subsided when the patient is first seen, and he is an otherwise healthy individual, operation may safely be deferred, but the appendix should be removed before he is allowed to get about again. In my experience an exception to this rule is justified in the case of patients past 50 years of age, for I have seen a fair number of such patients in whom the diagnosis was certain who have had no recurrence. This is not to say that operation should not be advised in patients past middle life if they are seen in an early or acute stage of the attack. On the contrary, it should be urged with more than usual force, for, if operation becomes imperative at a later stage, these middle-aged people do not stand it as well as healthy young adults do. *A fortiori*, early operation should be strongly urged in the case of children, for not only is there a tendency to rapid gangrene or abscess formation, with little attempt at localization, in these young people, but their small body weight makes them bad subjects for the resisting of an acute septic infection.

If the patient is unsuitable for operation, or if operation is refused, we must, of course, trust to palliative treatment, and I know of no better treatment than that which I have already recommended to be carried out while we are doubtful of the diagnosis at an early stage of an acute attack: but if it has to be long continued the patient must be kept going with rectal feeding, etc. If and when, in either of these classes of patients, the case is getting progressively worse, we are faced with a very difficult problem. My own opinion is that in the case of a patient who is an altogether unsuitable subject for operation we should continue to do our best by palliative measures, and that hopeless operations should not be advised. If, on the other hand, delay in operation upon an otherwise suitable patient is due to his refusal to submit, we must do our best to make him submit, and we shall not often fail.

OPERATION.

Of the operation of interval appendicectomy I have nothing to say here, for I have no knowledge that is not generally known, and no methods that are not generally practised. In acute cases my drainage procedure has been considerably modified in recent years, and now follows the lines indicated to me by Mr. Upcott of Hull. I always employ the usual oblique incision, excepting when I am in some doubt as to the appendix being the guilty organ with which I have to deal. I then use a right rectus incision. I have called my incision the usual oblique incision, instead of McBurney's, because the latter implies separation, rather than division, of the fibres of the deep muscles, and I do not always separate them. If the case is an early one and a first attack—that is, if I have reason to believe that the appendix is still freely movable and can readily be drawn out of the peritoneal cavity—I do separate the fibres of the internal oblique and transversalis: but if I am doubtful of its mobility, or there is a palpable swelling, I divide them. As a matter of fact, I have no particular preference for either method, and rarely decide which I shall employ until I am commencing the operation.

Having opened the peritoneum, one of many conditions may present itself.

1. We may open directly into a local abscess adherent to the anterior abdominal wall.

In this event the wisest course is to mop out the pus gently with gauze, insert a drainage tube, close the remainder of the wound, and apply warm moist dressings, leaving the removal of the appendix to a later date. In the cases of such local abscesses in children a single drainage tube may not be a sufficient drain, and it may be found wiser to leave the whole parietal wound open, lightly stuffing the whole abscess cavity with gauze. The same course should be adopted in local abscesses in children

which are not adherent to the anterior abdominal wall, or, better still, the abscess, before it is opened, should be made adherent to the parietal peritoneum by means of a few sutures of fine catgut. Whatever course is adopted, it cannot be too strongly insisted upon that in all cases of appendix abscess in children in which the appendix is not removed at the primary operation efficient, and even more than sufficient, drainage must be provided.

Instead of opening directly into a local abscess we may find:

2. The appendix acutely inflamed, or gangrenous, but unperforated, and freely movable; or,
3. The appendix acutely inflamed, or gangrenous, unperforated, but densely buried in adhesions; or,
4. The appendix acutely inflamed, or gangrenous, but perforated, and freely movable, with more or less extensive suppurative peritonitis; or,
5. The appendix acutely inflamed, or gangrenous, and perforated, but shut up inside a local abscess not adherent to the anterior abdominal wall; or,
6. Generalized purulent peritonitis

In either of the second, third, fourth, or fifth event the appendix should be removed unless there is some strong reason for its being left behind. In the unfortunate event of a general suppurative peritonitis being disclosed the appendix itself has probably spent its virulence, and in view of the value of time it can well be left alone unless it presents itself in the wound; certainly no prolonged search should be made for it.

It is of the method of dealing with the parietal wound after the removal of the appendix that I wish to write in detail. In my undergraduate and house-surgeon days we were taught that anything, even sterile blood, was a dangerous foreign body in the peritoneal cavity, and, as such, must on no account be enclosed. Consequently, extensive drainage by tubes and gauze was employed in all cases where it was thought that there was any chance of the peritoneum being even locally infected, as in the case of acute unperforated appendicitis; or soiled with blood from a ruptured ectopic pregnancy. I always held, even before much effort was made to prove it, that this lack of faith in the peritoneum was unjustified, as it seemed to me highly probable that Nature would make the greatest provision for the resistance of infection in those regions where successful invasion would lead to the greatest disaster. Furthermore, it was no uncommon event in the "clean" cases of those days to find superficial suppuration in the wound without any evidence whatever of peritoneal infection: which fact, as I always maintained, was a sufficient proof that the peritoneum was by no means the least resistant structure to bacterial invasion. Still, early teaching dies hard, and I continued to drain many things, I am sure, quite unnecessarily.

For many years I have aimed at the elimination of the drainage tube from the general peritoneal cavity. It is a long time since it disappeared in cases of blood soiling, and for several years I have closed the abdomen completely in cases of perforated gastric or duodenal ulcer, pyosalpinx, etc., and with the happiest results. Until December, 1921, I still retained it in cases of suppurative appendicitis, and, although I had got down to smaller and smaller tubes, I had never had the courage to close the peritoneum completely when appendix pus had been present. Before this time I had noticed that the after-history of an appendix abscess, in which I had removed the appendix, cleansed the peritoneum, and inserted a tube, was as follows.

For the first day there was a fairly profuse discharge of blood-stained serum. The wound then remained dry until the third day, when it commenced to suppurate, and there was more or less free discharge of pus through and from around the tube. With the commencement of this suppuration there was a considerable improvement in the patient's general condition, so much so that we looked anxiously for pus to appear, and felt that at last we knew what our predecessors meant when they spoke of laudable pus. When suppuration was established the tube was removed, cleansed, and reinserted for a longer or shorter period, and we had to deal with a suppurating wound of the extent of the drain track and the infected parietal parts, which wound was healed in four weeks.

Our results were good, in that the patients recovered, and we only had a very small number of incisional hernias to deal with later, but I felt that we had not reached finality, and that there was a pathological process at work that we were not understanding, for there should be some way of preventing this secondary suppuration in the abscess cavity.

In the light of the results of my present treatment the solution is easy, for it is beyond doubt that there had been no secondary suppuration in the abscess cavity itself, but a secondary infection of the tube track from the suppuration of the abdominal wall; that, in fact, instead of being beneficial, the insertion of the tube had been actually harmful.

For the institution of my present methods I am indebted to Mr. Upcott. In the autumn of 1921 a letter from him on the subject was published in the *British Medical Journal*, and he very kindly gave me fuller particulars of his technique, and his reasons for it. The stages are as follows; the description applying to the cases in class 5, where the appendix is perforated, and lies embedded in a local abscess not adherent to the anterior abdominal wall. Suitable modifications are made as required for cases in classes 2, 3, and 4, the essence of the method being that whenever the appendix is removed the peritoneum is closed, except in cases of general suppurative peritonitis.

1. An incision that inflicts the least amount of trauma on the abdominal wall.
2. The free peritoneal cavity is packed off with strips of gauze.
3. Adhesions are separated until the abscess is opened, when the pus is mopped up as fast as it escapes, and the abscess cavity is carefully dried.
4. The appendix is removed.
5. A fresh piece of gauze is placed in the abscess cavity, and the original packing removed. Any collection of pus in the pelvis or kidney pouch is carefully mopped up.
6. The gauze is removed from the abscess cavity, and the peritoneum completely closed with a continuous catgut suture.
7. The muscular and aponeurotic layers are closed with interrupted catgut sutures, an interval being left for the emergence of a strip of rubber half an inch wide, which is laid along the peritoneal suture line. The skin is closed with silkworm-gut, excepting for the small space left for the rubber strip.
8. A dressing wet with 5 per cent. saline, to encourage exudation, is applied. This should not be changed for two or three days.

Excepting that I have not always, nor usually, left the saline dressing unchanged for two or three days, I have carried out this technique with the most satisfactory results, immediate and remote, and on only two occasions since December, 1921, have I inserted a drainage tube into the peritoneal cavity when I have removed the appendix. These exceptions were not because of weakening faith, but because in these two cases the whole of the appendix was gangrenous and sloughing, necessitating the removal of an ellipse from the wall of the caecum, and I dared not place unlimited faith in my suture line. As a matter of fact in both cases all was well, and there was no fistula.

There is nearly always some suppuration, but it is entirely extraperitoneal, and is much more limited in amount than it was when a tube was inserted into the abscess cavity. The peritoneum has looked after itself; healing is by at least a week more rapid; and the resulting scar is more firm. Though it is not the matter of first importance when one is dealing with a life-saving operation, it is an interest and satisfaction that, so far as I know, no patient has developed a ventral hernia after this operation.

In the hope of further advance and greater safety in healing I have tried various methods of preventing this muscle suppuration. I have used hipp, spirit, eusol, etc., but I cannot say that any of them has been helpful, and I have abandoned their use almost entirely. Very occasionally I give the abscess cavity a final mop out with gauze wet with eusol, and it may, or may not, be helpful.

I have also drained the muscle layers in all acute cases in which the appendix is not perforated. In these cases the rubber strip is removed in forty-eight hours, when it has served the very useful purpose of allowing the postoperative serous exudate to escape into the dressings. A primary union has invariably resulted. I am sure that this

is a wise proceeding. Since first doing it I have had no trouble whatever with the abdominal wall, and when the sutures are removed it is impossible to recognize any evidence of the use of a drain; whereas, if the wound is completely closed at the time of the operation, there is at least some risk of suppuration among the muscles, with, possibly, serious extension.

For the employment of this method Mr. Upcott's reasoning was that serous membranes are tissues specially organized for protection against infection, and that they can be safely left to perform this function. On the other hand, muscles have specialized for the one function of movement, and fall a ready prey to microbic infection. I am fully convinced, both by theory and practice, that these views are sound. As a final proof that they are I asked Dr. Cookson, pathologist to the Sunderland Royal Infirmary, to make some observations for me. This he very kindly did.

He provided me with six culture tubes, and during an emergency operation upon a case of acute appendix abscess one of our residents inoculated these as follows. The first from the wound as soon as I had made the superficial incision. The second from beneath the external oblique muscle. The third from beneath the deep muscles. The fourth from the peritoneal cavity before the abscess was opened. The fifth from the abscess cavity. The sixth from the muscles after the peritoneum was closed. Dr. Cookson reported that numbers one, two, three, and four were sterile; numbers five and six were infected. Number five would necessarily be so, and although the fact of number six being infected completely confirmed the above views, it was somewhat surprising, for I had endeavoured to protect the muscles very carefully during operation. It was certainly instructive.

The following are the analyses of my cases.

TABLE I.—*Acute Cases in which the Appendix was Removed at the Primary Operation.*

Situation of the Appendix.	Appendix was not Perforated, and was Adherent.	Appendix was not Perforated, but was Adherent.	Appendix was Perforated, and was not Adherent.	Appendix was Perforated in a Local Abscess.	Died.	Total.
Internal to caecum and in front of ileum	69	28	2	11	0	110
Internal to caecum and behind ileum	18	8	5	17	1	49
External to caecum	25	12	8	24	0	69
Retrocaecal	45	25	11	42	0	131
Towards pelvic brim ...	45	12	17	6	0	80
In true pelvis	23	16	10	15	3	67
Totals	226	111	53	115	4	509

TABLE II.—*Acute Cases in which the Appendix was not Removed at the Primary Operation.*

	Recovered.	Died.	Total.
Circumscribed local abscess	26	1	27
Diffuse general suppurative peritonitis ...	7	6	13
Totals	33	7	40

TABLE III.—*Interval and Subacute (Resolving) Cases.*

Situation of the Appendix.	Not adherent.	Adherent.	Died.	Total.
Internal to caecum and in front of ileum	49	36	0	85
Internal to caecum and behind ileum	7	18	0	25
External to caecum	5	18	0	23
Retrocaecal	7	47	0	54
Towards pelvic brim	30	14	0	44
In true pelvis	4	16	0	20
Totals	102	149	0	251

In the interval cases and subacute cases there were no deaths, and if we confine the death rate to the acute cases it is exactly 2 per cent. If, however, we eliminate the cases of diffuse suppurative peritonitis we have a death rate of 0 per cent. for interval and subacute cases; of 0.93 per cent. for the whole of the acute cases; and of 0.64 per cent. for all cases.

By general peritonitis in the above list is meant diffuse suppurative peritonitis, in which the peritoneal cavity contained pints of pus, in which the appendix was neither seen nor searched for, and in which the only operative procedure was the introduction of drainage tubes. Each of these patients had been ill for more than a week before admission, and in only one was the appendix ever seen at all, and that was post mortem; but the history of the cases left no doubt in my mind that the appendix was the cause of the peritonitis. Naturally, in such cases, there was a very high mortality, and I was very thankful that seven out of thirteen cases recovered.

It is obvious that lesser degrees of suppurative peritonitis were present in all the cases where the appendix was perforated and free—that is, fifty-three cases—and the amount of free pus varied from a few drachms to two pints. These cases accounted for two further deaths, in both cases the appendix being pelvic, while a perforated appendix in a local pelvic abscess accounted for a third. Another death resulted from acute obstruction which came on five days after the removal of an acutely inflamed appendix adherent behind the lower end of the ileum, while the remaining death occurred in a healthy woman, 30 years of age, who had been admitted to hospital with a large local abscess, adherent to the anterior abdominal wall. She had been ill for ten days before admission, and I simply incised the abscess and inserted a drain. A week later, during a satisfactory progress, she died suddenly from a pulmonary embolus.

Of the acute non-perforated appendices the degree of inflammation varied from acute catarrhal inflammation to complete gangrene. As the essential point is that they were not perforated no useful purpose would be served by further particularization.

Of the perforated appendices, 53—as already noted—were free, and 142 were in local abscesses of greater or lesser extent. Of these 142 cases, the appendix was removed at the primary operation in 115, whilst simple drainage was employed in 27. A subsequent appendicectomy was performed in 18 of the latter. In 7 cases the caecum was undescended, and in 2 of these the greatest difficulty was experienced in removal of the gangrenous appendix tucked up between the liver and the ribs.

I have limited my analysis to cases actually operated upon by me, and to all of those cases. Many others have been operated upon from my wards by my colleague Mr. G. S. Robinson, on similar lines, and with equally good results, and I am definitely and finally of the opinion that, once the appendix is removed, an intraperitoneal drain is entirely useless and unnecessary, and it may be harmful.

While I shall not be content to admit that the treatment of appendicitis is completely satisfactory until such time as the recovery rate is 100 per cent., I think I can fairly claim that the above results show a definitely favourable advance upon the generally accepted mortality rate; and that they justify my advocacy of immediate operation in all acute cases—with the aforementioned exceptions—and my faith in the peritoneum. It only remains for me to express my sense of the greatest indebtedness to those who have assisted me in attaining these results, and more particularly to my house-surgeons, and to the theatre and ward nursing staffs.

Since February, 1929, I have operated upon a further 112 cases, of which 70 were acute, and 42 were resolving, or interval. They are not analysed in detail, and would not have been noted at all but for the unfortunate fact that there were five deaths among them. The ages of the patients who died were respectively 53, 59, 15, 56, and 52 and all were gravely ill on admission. Adding these cases to the 400 detailed above we get a total of 912 cases, of all degrees of severity, with 16 deaths—a mortality rate for the whole number of 1.75 per cent.

CLINICAL EXPERIENCES WITH PERCAIN, A NEW LOCAL ANAESTHETIC.

BY

NORMAN C. LAKE, M.S., M.D., D.Sc., F.R.C.S.,
SURGEON TO CHARING CROSS HOSPITAL,

AND

C. JENNINGS MARSHALL, M.S., M.D., F.R.C.S.,
SURGEON WITH CHARGE OF OUT-PATIENTS, CHARING CROSS HOSPITAL.

LOCAL *anaesthesia—a term used in this article to cover* tissue infiltrations, nerve trunk and splanchnic blocks, and spinal anaesthesia, whether for the production of "anaesthesia" or "analgesia"—has not been, and possibly never will be, as popular in this country as on the Continent and in certain parts of the United States. This is probably largely owing to the traditional ideas established in the minds of the public, which make them less likely to co-operate willingly with the surgeon, and create a bias in favour of complete unconsciousness. It must be pointed out that the technique of local anaesthesia demands much more than the somewhat perfunctory attention usually paid to it; moreover, the special care that must be given to certain details in the performance of operations under local anaesthesia of necessity restricts the surgeon's freedom of action, and this may at times be considered a sufficiently grave inconvenience to outweigh any advantages the method might offer. The last point in its turn will depend upon the type of operation and the temperament of the surgeon.

Other things being equal, however, the disadvantages would be minimized if the local anaesthetic could conform with the following desiderata.

1. Practical non-toxicity in relatively large doses and the absence of idiosyncrasy.

2. Rapidity of action in order that the injection itself may be painless and that complete anaesthetization of the area may be induced within a reasonable period of time.

3. Good powers of diffusion and penetration.

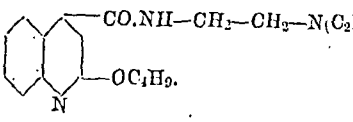
4. A duration of anaesthesia sufficient to enable the most extensive operation to be performed without reinjection.

5. An ideal quality would be a prolonged period of dulled sensibility after the anaesthetization proper had passed away.

6. There should be no impairment of tissue vitality or retardation of healing—a fatal defect of quinine and urea hydrochloride, a substance that exhibits the previously mentioned quality to a pronounced degree.

7. The substance should be readily eliminated.

In addition to these physiological properties the local anaesthetic should have the following physical characteristics.



1. It should be stable both in the solid and in the dissolved condition.

2. It should be unaffected by exposure to air, or by exposure to heat, for the purpose of sterilization; or by admixture with saline, adrenaline, and such substances as may reach it from the walls of vessels, instruments, and syringes.

3. For spinal injection it would be advantageous for the solution to be effective in such low concentration that the specific gravity could, if necessary, be made lower than that of the cerebro-spinal fluid—that is, about 1006. Inexpensiveness would, of course, be an added attraction.

The anaesthetic group in use at the present time (the novocain group) possesses many of these characteristics and gives on the whole considerable satisfaction. Among the chief disadvantages, however, are the following: the anaesthesia, even in conjunction with adrenaline, is not sufficiently long for the performance of some major operations, so that reinjections of the mes necessary; there is no post-operative anaesthesound waed sometimes there is abnormal post-operative pain bd, in t be admitted that this is due we only had a very small emostasis, which must be meticulous when adrenaline is used, or to the employment of heterotonic solutions); it is liable to destruction by oxidation, is none too stable on heating, and is very labile in the presence of even traces of alkalis. In contrast with cocaine, its action on intact mucous and other surfaces, such as the conjunctiva, nasal mucosa, and urethra, is lamentably inferior. Its mild vaso-dilator action is readily counteracted by the use of adrenaline.

We have recently tried in a considerable number of cases of all types a new local anaesthetic, percain, made by Ciba of Basle, and handled in this country by the Clayton Aniline Company. Percain is a quinoline derivative, being the hydrochloride of diethyl-ethylene diamide of alpha-butyl oxycinchoninic acid, with the structural formula

It forms colourless crystals soluble in water; the solution may be sterilized without deterioration by boiling. In the preparation of such solutions, however, care must be taken that no alkali comes into contact with them lest precipitation should occur, a particularly serious event where the concentration is so low. Glass free from alkali should be used, and the saline prepared with doubly distilled water, containing no trace of sodium carbonate or bicarbonate; accidental contamination by these may be countered, however, by the addition of a minute quantity of dilute hydrochloric acid—for example, two or three drops per litre. Percain is miscible with adrenaline. The specific gravity of effective dilute solutions in water may be as low as 1002, and, therefore, by the use of varying degrees of tonicity of saline, solutions of any specific gravity likely to be desired can be produced. This, it should be realized, is the first time that a watery solution of anaesthetic having a specific gravity either equal to or even appreciably less than that of the cerebro-spinal fluid has been available. This fact promises to revolutionize the whole technique of spinal anaesthesia, since it enables anaesthesias to predetermined levels to be obtained with reasonable certainty. The special methods adopted to obtain high-level anaesthesia with percain are at present being standardized by Dr. Howard Jones, senior anaesthetist to Charing Cross Hospital.

The following are the outstanding physiological qualities that attracted attention. (1) The extreme degrees of dilution in which the drug is capable of producing efficient anaesthesia. (2) The prolonged period of action. With regard to the former, its effective concentration on the cornea of the rabbit is 1 in 120,000, compared with 1 in 15,000 for cocaine; weight for weight, therefore, it is easily the most powerful local anaesthetic known. Against this it must be admitted that percain is far from being non-toxic, a subcutaneous dose of 0.01 gram per kilo being lethal to the rabbit, giving rise to excitement, dyspnoea, and cramps, with death from respiratory paralysis; rapid intravenous injection is fatal in a dose of 0.0045 gram per kilo. This may be compared with the following figures for other local anaesthetics: cocaine, injected slowly intravenously in the rabbit, 0.019 gram per kilo; cocaine hypodermically in dogs, 0.025 per kilo; novocain intravenously in rabbits, 0.06 per kilo. The British Medical Association Committee's scale of relative toxicities is as follows: cocaine 1.0; stovaine 0.625; novocain 0.49; beta-eucaine 0.414. (Allen, however, gives the toxicity of novocain as being six to seven times less than that of cocaine.) On this scale, therefore, percain would stand at about 4.0.

Percain shows inhibition of bacterial growth, but in the concentrations employed is not definitely bactericidal. Hofer states that its minimal effective concentration in the rabbit subcutaneously is 1 in 140,000, and that "there seems to be a particular sensitivity of the splanchnic system to the preparation, these vessels being enormously swollen in the killed animal." Owing, however, to the extreme intensity of its action there would appear to be not the slightest likelihood of anything approaching the lethal dose being needed for operative procedures. There is, further, as far as can be ascertained, no record of

such personal idiosyncrasy as is notorious in the case of cocaine.

With regard to the second quality—namely, prolonged period of action—percain is surpassed only, though easily, by quinine and urea hydrochloride; this last substance, however, has two almost insuperable contraindications—its painful induction and sometimes disastrous local toxic effects. With percain a duration of anaesthesia of between two and six hours, according to the concentration, is alleged to be obtained.

Personal Tests.

We have tested the anaesthetic properties of percain upon ourselves, with the following results. The intradermal injection (1 in 2,000 without adrenaline) produced immediate and complete insensitivity lasting about two and a half hours. Subcutaneous infiltration (without massage or kneading, which we have found to accelerate induction) was followed by anaesthesia in about five minutes, lasting over three and a half hours. In neither case was there subsequent hyperaesthesia or dermal change (for example, desquamation). In the intradermic, and to a less extent in the subcutaneous injections, there was an immediate severe hyperaemia coterminous with the anaesthesia. In the infiltration of a small subcutaneous nerve (perineural infiltration with the same concentration) there was anaesthesia in about twelve minutes, lasting over five hours.

Clinical Experiences.

Our experience, which now extends over four months, would appear to support the claims made. The substance has been employed in local infiltration (of the Schleich type), nerve blocks, paravertebral anaesthesia, splanchnic blocks, and spinal anaesthesia. The concentrations used have been 1 in 1,000 to 1 in 2,000. It is usually recommended that ten minims of adrenaline (1 in 1,000) to each ounce of local anaesthetic solution is the appropriate dose; we find that this may be doubled or even trebled with no deleterious effect, but with greatly enhanced convenience as regards speed and intensity of action. The addition of adrenaline is essential, as without it percain seems to have a much greater local vaso-dilator action than novocain. In the above concentrations we have frequently employed three or four ounces of solution; in one instance seven and a half ounces were used (this was a partial gastrectomy with parietal and splanchnic infiltrations; the concentration was 1 in 1,500, and the total quantity, therefore, about 2 grains).

In the considerable number of cases now dealt with we have observed no evidence of toxic effect, either general or local; there has been no undue tissue reaction and no impairment of healing after any local infiltration. Thiersch grafts removed under subcutaneous infiltration (1 in 2,000) take in a perfectly normal manner. There has been no evidence of neuritis or impaired conduction after any nerve block.

When due attention is paid to the special points to be observed in all operations under local anaesthesia—for example, avoidance of traction on structures attached outside the infiltrated field—the procedures could be carried through without giving pain to the patient. Phenomena of sensory dissociation are quite frequent, painful sensation always being lost, but that of pressure and touch sometimes being retained. This, of course, is commonly observed in all forms of local anaesthesia, although never to the same startling extent as with small spinal injections. Post-operative anaesthesia was uniformly seen, varying from three to six hours. This admittedly falls short of the ideal, which would have a duration of several days; but nevertheless it is sufficient to confer a very distinct advantage.

A detailed list of the cases in which percain has been used would be tedious and unnecessary; the following summary will, however, indicate the practically unrestricted scope of the preparation. Finger operations (infiltration of root); Dupuytren's contracture (wrist infiltration and ulnar and median block); simple subcutaneous tumours; diagnostic removal of glands; oral anaesthesia for radium (lingual and dental nerve blocks); scalp anaesthesias, Thiersch grafts, sympathectomy, herniorrhaphies, varicocele and hydrocele operations, anal operations, simple mastectomy, ventriculography, colostomy. Among the more extensive procedures are: gastro-enterostomy, gastrostomy, appendicectomy, cholecystectomy (with a localized splanchnic block in addition), gastrectomies, thyroidectomies, pituitrectomies. In these, general hypnotics have, in addition, been administered—hyoscine or morphine.

Surface Anaesthesia.

We have no experience of percain in its application to the conjunctiva and to the nasal mucosa. It has been repeatedly employed in a 1 in 1,500 concentration to the urethral mucosa for the performance of cystoscopy—but has not seemed quite equal in intensity to the usual cocaine-chloretone combination.

Spinal Anaesthesia.

While percain can be claimed to show a distinct advance on previous local anaesthetics in its application to infiltration and nerve-blocking anaesthesia, there can be no doubt that its greatest attraction lies in the special advantages it confers in spinal anaesthesia. These are the duration of action and the low specific gravity of effective solutions. The latter characteristic has made necessary and possible some important modifications of the usual technique of administration: these, as has already been stated, are still in process of standardization, and will therefore not be dealt with fully in this article. Our experience of some hundred cases, however, enables us to make certain positive statements. The anaesthesia takes somewhat longer to develop than that with novocain, but the rate varies, of course, with the concentration employed. It may last anywhere up to six hours, again depending on dose and concentration. As an indication of the extent of action it may be stated that complete anaesthetization of the abdomen, including the splanchnic nerves, may be obtained by the injection of 12 to 16 c.cm. of a 1 in 2,000 solution at the first or second lumbar interspace. The most prolonged abdominal operation may therefore be performed under intrathecal injection alone. The anaesthesia has persisted several hours after the completion of resection for gastro-jejunal ulceration, the abdomino-perineal removal of the rectum, and operations of like severity.

The fall of blood pressure produced by splanchnic paralysis is probably less severe than with novocain, though, of course, it lasts much longer; it can to a large extent be overcome by administration of ephedrine, but particular care must be taken of the posturing of the patient for many hours after the operation is completed. It may be emphatically stated, however, that in this long series of cases no instance of serious vasomotor collapse has been met with such as to give rise to the least anxiety or to call for any special treatment. The early sickness which is so common with novocain injections is relatively infrequent with percain, as are also post-operative headaches.

Sensory and motor dissociations have been observed apparently in a greater proportion of cases than with other intrathecal agents, possibly in part owing to the very low specific gravity of the solution. No irritant effects on nerve roots or cord have been observed. The upper level of action has been sufficiently high in some cases to cause numbness and tingling of the hands; the need for caution with regard to the avoidance of phrenic paralysis when using a drug with a four hours' action is obvious. So far, at any rate, the trouble has not arisen.

Conclusions.

Weight for weight, percain is less expensive than novocain, and when the dilution is taken into account (0.075 to 0.05 per cent. as compared with 0.5 per cent.), it is very much cheaper. Contrasted with ether and gas and oxygen the cost per patient is infinitesimal.

As a result of our experience we are led to conclude that percain marks a definite advance over existing local anaesthetic substances, and particularly we believe that it promises to mark a very considerable advance in spinal anaesthesia.

A STUDY OF THE TENDENCY TOWARDS DELINQUENCY OF BACKWARD CHILDREN.

BY

R. G. GORDON, M.D., D.Sc., F.R.C.P.Ed., R. E. THOMAS, M.D., D.P.H.,

AND

MISS E. G. GREENALL,

OF THE BATH CHILD GUIDANCE CLINIC.

In discussions on juvenile delinquency it is often stated that mental defect and mental backwardness are associated closely with misconduct in the child. So far as certifiable mental defect is concerned, Professor Burt has laid it down that not more than 7 per cent. of juvenile delinquents are mentally defective within the meaning of the Act. Although there have been some authorities who have put the percentage as high as 20, most now find themselves pretty well in agreement with Professor Burt's figures, but it is frequently stated that if mental defect is not closely associated with delinquency, the moron or backward child often shows asocial conduct. This appears to be one of those generalizations which are not supported by carefully worked out statistics, and it seems desirable to bring forward some evidence as to whether this is the case or not. If such is to be adduced, we must not estimate how many delinquents are backward, but try to determine how many backward children become delinquent. An opportunity to do something towards this end was afforded by the fact that during the last nine years several cases have been referred from the schools of the city of Bath to Dr. Thomas, the deputy school medical officer, as supposedly defective. One hundred of these children who were not found to be certifiable under the Act, and were therefore not placed in a special school, have been carefully investigated and followed up. The appended figures give a summary of the result of this investigation.

NUMERICAL SUMMARY OF FINDINGS.

Children reported by school masters and mistresses as probably subnormal = 100 (boys 56, girls 44).

BOYS.

At the date of the inquiry the ages of the 56 boys ranged from 22 to 8. Of these, 1 showed an I.Q. (intelligence quotient) of 60–70 per cent.; 18 an I.Q. of 70–80 per cent.; 27 an I.Q. of 80–90 per cent.; 9 an I.Q. of 90–100 per cent.; while 1 showed an I.Q. of 116 per cent.

Conduct in School.

Forty boys showed good conduct in school: 16 were complained of in some way or another; 10 were noted as asocial with other children at school—that is, were either leaders in mischief, spiteful with other children, or too easily led; 15 were noted as unsatisfactory in their conduct in the home.

Of the troublesome cases, 5 were noted as causing difficulty both at home and in the school; 11 were troublesome in school, but good at home; and 10 were troublesome at home, but good in school.

Of the 10 who were asocial with other children, 3 showed a correlation with complaints from both the home and the school; 3 with complaints from the home; 2 with complaints from the school; and 2 without complaints from either.

During their school period, therefore, 28 showed some abnormality in conduct—that is, 50 per cent. Of these, 7 were noticed to have some defect of physical health—that is, 25 per cent.—but, of the well-behaved boys, 11 were noted to have a defect of physical health—that is, 39 per cent.

In 18 cases there was a broken parental relationship. By this is meant that either the father or mother was dead or separated. Of these, 13 cases showed conduct disorder. Of the 5 cases who showed no conduct disorder, 1 had neither parent and was in a home; in 1 case the father had deserted; and in 3 cases the father was dead. Of the 13 cases with conduct disorder, 4 had lost both parents, 5 had lost their father, and 4 had lost their mother.

Family History.

With regard to the family history: in 24 cases nervous or mental manifestations were noted. Of these, 8 had some sort of conduct disorder, and 16 were of good conduct. In 3 cases there was pronounced physical ill health in the family. Of these, 1 showed conduct disorder and 2 were of good conduct. In 6 cases, one or more members of the family were certified as mentally deficient. Of these, 3 showed conduct disorder and 3 were of good conduct.

The home conditions were reported as bad in 6 cases. Of these, 4 showed conduct disorder, and 2 were of good conduct. One boy had had encephalitis lethargica, but there was no conduct disorder, either at school or later.

In one boy, who showed conduct disorder in all respects, there was a history that his family had had a very bad experience during the Irish revolution, which had left a strong emotional impression on the boy. This is the boy referred to below, who was sent to a Home Office school and is only now doing well. He had no special treatment.

Of the 56 boys examined, 37 have now left school, and of these 17 showed no conduct disorder while at school, and 20 gave some trouble of one sort or another. It has been impossible to trace 4 cases, 3 of whom had shown conduct disorder at school.

Of the 16 who have been traced who showed no trouble during school age, none have given any trouble since leaving school: 13 are in work and are doing well; 2 have had work and did well in it, but are now out of work; 1 has so far found no work.

Of the 17 who have been traced and had given trouble during school age, 10 are in work and doing well; 3 have had work and did well in it, but are now out of work; 1 had work and was fairly satisfactory, but is now out of work; 1 has definitely been dismissed for misconduct; 1 is a waster and has never got work; 1 got into the hands of the police for stealing, was sent to a reformatory school, from which he tried to escape, and his term therefore was lengthened; he is now reported as of good conduct.

Of the 37 supposedly defective boys who have left school, 4 cannot be traced; 23 are in work and are doing well; 5 have had work and done well, but are at present out of work; 1 has had work and was fairly satisfactory, but is at present out of work; 3, one of whom has had work, have been definitely unsatisfactory, though one is now reported as having improved, and one has not yet found work, but is of good conduct. One boy 100 per cent. I.Q. is doing very well in a garage.

The boy with 116 per cent. I.Q. behaved well at school, but was uncontrolled at home and pilfered. His father had died in an asylum, his mother was nervous, and he was sent to a training ship, where he is training for the navy and apparently doing well.

The following list shows the types of employment: errand boy, 8, factory worker, 5; milkman, 3; gardener, 2; farm worker, 2; motor mechanic, 2; grocer, 2; warehouseman, 1; clerk, 1; chair-maker, 1; labourer, 1; soldier, 1; page-boy, 1; total 30.

GIRLS.

At the date of the inquiry the ages of the 44 girls ranged from 22 to 8. Of these, 2 showed an I.Q. of 60–70 per cent.; 16 an I.Q. of 70–80 per cent.; 22 an I.Q. of 80–90 per cent.; 3 an I.Q. of 90–100 per cent.; while 1 showed an I.Q. of 130 per cent.

Conduct in School.

Twenty-four girls showed good conduct in school; 20 were complained of in some way or another; 14 were noted as asocial with other children at school; 10 were noted as unsatisfactory in their conduct in the home.

Of the troublesome cases 7 were noted as causing difficulty both at home and in the school; 13 were troublesome in school, but good at home; 3 were troublesome at home, but good in school.

Of the 14 who were asocial with other children, 5 showed a correlation with complaints from both the home and the school; 2 with complaints from the home; 4 with complaints from the school; 3 without complaints from either.

During their school period, therefore, 26 showed some abnormality in conduct—that is, 59 per cent. Of these, 6 were noticed to have some defect of physical health—that is, 23 per cent., about the average for the total school population—but of the well-behaved girls 6 were also noted to have a defect of physical health—that is, 33 per cent. Of the 12 cases of defect in physical health 5 suffered from rheumatic infection; 3 of these had conduct defect and 2 were without conduct disorder.

In 17 cases there was a broken parental relationship. By this is meant that either the father or mother was dead or separated. Of these, 9 cases showed conduct disorder. Of the 8 cases who showed no conduct disorder, 1 had lost both parents; in 7 cases the father was either dead or unknown. Of the 9 cases with conduct disorder, 6 had lost both parents and were either boarded out or in homes; 2 had lost their father; 1 had lost her mother.

Family History.

With regard to the family history: In 9 cases nervous or mental manifestations were noted. Of these, 7 had some sort of conduct disorder, and 2 were of good conduct. In 7 cases there was pronounced physical ill health in the family. Of these, 2 showed conduct disorder and 5 were of good conduct. In 9 cases one or more members of the family were certified as mentally deficient. Of these, 7 showed conduct disorder, and 2 were of good conduct.

The home conditions were reported as bad in 10 cases. Of these, 7 showed conduct disorder, and 2 were of good conduct.

Of the 44 girls examined 36 have now left school, and of these 9 showed no conduct disorder while at school, and 21 gave some trouble of one sort or another. It has been impossible to trace 2 cases, one of whom showed conduct disorder at school.

Of the 8 who have been traced who showed no trouble during school age, none have given any trouble since leaving school: 7 are in work and are doing well, and one has been married for a year.

Of the 20 who have been traced and had given trouble during school age, 16 are in work and doing well: 1 has had work and did well in it, but is now out of work; 1 had work but was dismissed for misconduct; 1 cannot get work; and 1 is in a mental institution.

Of the 30 supposedly defective girls who have left school, 2 cannot be traced; 23 are in work and are doing well; 1 is married; 1 had work and did well, but is at present out of work; 1 cannot find work; 1 has had work and proved definitely unsatisfactory; and 1 is in a mental institution.

One girl 100 per cent. I.Q. showed no conduct disorder and is now in steady work. The girl with 130 per cent. I.Q. gave a considerable amount of trouble, both at school and at home, from pilfering and lying, but on being removed to another school the mistress gave her positions of trust and her conduct improved very markedly.

The following list shows the types of employment: domestic service, 11; factory worker, 5; tailoress, 3; barmaid, 2; waitress, 1; laundress, 1; nursemaid, 1; gardener, 1; messenger girl, 1; total, 26.

BOTH BOYS AND GIRLS.

Taking boys and girls together, at the date of the inquiry the ages of the 100 children ranged from 22 to 8. Of these, 3 showed an I.Q. of 60–70 per cent.; 34 an I.Q. of 70–80 per cent.; 49 an I.Q. of 80–90 per cent.; 12 an I.Q. of 90–100 per cent.; 1 an I.Q. of 116 per cent., and 1 an I.Q. of 130 per cent.

Conduct in School.

Sixty-four children showed good conduct in school; 36 were complained of in some way or another; 24 were noted as asocial with other children at school; 25 were noted as unsatisfactory in their conduct in the home.

Of the troublesome cases, 12 were noted as causing difficulty both at home and in school; 24 were troublesome in school, but good at home; 13 were troublesome at home, but good in school.

Of the 24 who were asocial with other children, 8 showed a correlation with complaints from both the home and the school; 5 with complaints from the home; 6 with complaints from the school; 5 without complaints from either.

During their school period 54 showed some abnormality in conduct. Of these, 13 (24 per cent.) were noticed to have some defect of physical health, but of the well-behaved children 17 (37 per cent.) were noted to have a defect of physical health.

In 35 cases there was a broken parental relationship. Of these, 22 showed conduct disorder. Of the 13 cases who showed no conduct disorder 2 had lost both parents and in 11 cases the father was either dead or unknown. Of the 22 cases with conduct disorder 10 had lost both parents, 7 had lost their father, and 5 had lost their mother.

Family History.

With regard to the family history: in 33 cases nervous or mental manifestations were noted. Of these, 15 had some sort of conduct disorder and 18 were of good conduct. In 10 cases there was pronounced physical ill health in the family. Of these, 3 showed conduct disorder, and 7 were of good conduct. In 15 cases one or more members of the family were certified as mentally deficient. Of these, 10 showed conduct disorder and 5 were of good conduct.

The home conditions were reported as bad in 16 cases. Of these, 11 showed conduct disorder and 4 were of good conduct.

Of the 100 children examined, 67 have now left school, and of these 26 showed no conduct disorder while at school, and 41 gave some trouble of one sort or another. It has been impossible to trace 6 cases, 4 of whom had shown conduct disorder at school.

Of the 24 cases that have been traced who showed no trouble during school age, none have given any trouble since leaving school; 20 are in work and are doing well; 2 have had work and did well in it, but are now out of work; 1 has so far found no work, and 1 girl has married.

Of the 37 that have been traced and had given trouble during school age, 26 are in work and doing well; 4 have had work and did well in it, but are now out of work; 1 had work and was fairly satisfactory, but is now out of work; 2 have been dismissed from work for misconduct; 1 cannot get work; 1 is a waster and has never got work; 1 got into the hands of the police and was sent to a reformatory school; and 1 is in a mental institution.

Of the 67 supposedly defective children who have left school, 6 cannot be traced; 46 are in work and are doing well; 6 have had work and done well, but are at present out of work; 1 has had work and was fairly satisfactory, but is at present out of work; 4, two of whom have had work, have been definitely unsatisfactory; 1 girl is married; 1 cannot find work, and 1 is in a mental institution.

Two children who proved normal—that is, 100 per cent. I.Q.—have done well and given no trouble. Two children who were supernormal gave trouble through pilfering and lying at an early age, but when put into better circumstances their conduct has improved and they seem to be turning out well.

In considering these figures it is perhaps worthy of note that most, if not all, these children were of the type who might well be sent to child guidance clinics as at present established and being established in many centres. With the exception of one or two, none of them received the specially organized treatment which is offered at these clinics, although in many cases they were the subjects of particular care on the part of both the teachers and the school medical department. None the less, the striking feature of the whole investigation is that adaptation to environment was difficult to a large proportion of them at school age, but 90 per cent. of them succeeded later in adapting themselves. This would seem to indicate that the enthusiasts for child guidance, amongst whom the present authors count themselves, should not make too extravagant claims for their methods. It is sometimes implied in the publicity notices of child guidance clinics—not with more particularly in other countries than this—that but for child guidance the younger generation must grow up neurotic, criminal, and maladjusted; but former generations have lied and stolen and played truant in their youth and yet grown up to figure wonderfully well in the struggle for civilized existence. Should we therefore hold with certain opponents of child guidance who maintain that the whole thing is a fad and of no practical service to the community? It would seem that the truth lies somewhere between these extremes, for it certainly does not benefit the individual or the community that pilfering, lying, or truancy should continue any longer than absolutely necessary, even though in many cases a successful adaptation may be made later. Further, if, as is generally admitted, specialist clinics are desirable for children for various physical disabilities, specialist clinics for mental disabilities are also necessary. Another interesting feature of the early difficulty of adaptation and later relative success is that it corresponds with certain, so far unpublished, observations of Dr. Thomas on the progress of mental development of certified mental defectives who, when they are at such a low level as to come within the official designation of feeble-minded, do progress rather than remain, as is sometimes supposed, at a constant level. Since mental defect is held by the recent departmental committee to consist more of difficulty in social adaptation than of intellectual incapacity, this slow development of adaptability in these backward children is characteristic. It also supports our opinion that no very elaborate treatment is necessary in child guidance work.

Certain other factors are brought out by the inquiry. The presence of physical disability did not show any marked correlation with conduct disorders. The chief influences in association with maladaptation were bad homes, broken parental relationship—though the absence of the father did not seem to make for trouble in any special degree—and what might be described as a psychopathic family history. The presence of nervous and mental disabilities or mental defect in other members of the family showed a high correlation with misconduct. The poor adaptation made by the two supernormal children is interesting; in one case—the boy—there is a definite psychopathic trait, while in the case of the girl it would seem that the routine work of early school life which was below her capacity failed to awake and hold her interest.

OSTEITIS DEFORMANS: ITS TREATMENT BY ULTRA-VIOLET RAYS.

BY

CLEMENT NICORY, M.R.C.S., L.R.C.P.,

PHYSICIAN, PHYSICAL TREATMENT CENTRE, BRITISH RED CROSS SOCIETY, KENSINGTON DIVISION.

OSTEITIS deformans was described for the first time by Paget in 1876, but nothing is known about its etiology. It is seldom seen before the age of 40, and is equally common in males and females. The main symptom is pain, which is attributed to rheumatism in most cases. The disease is frequently overlooked until gross deformity appears, or an *x*-ray photograph is taken.

Pathology.

The normal bone rarefies, and is slowly invaded by fibrous tissue, leading to softening and bending. Coincident with this destruction some regeneration and ossification occur at a slow rate. In the long bones the normal curves are exaggerated at first, and later abnormal curves make their appearance. The subperiosteal bone laid down is more porous, roughened on the surface, and considerably larger than the normal.

The long bones of the lower extremities, the pelvic bones, and the skull are most commonly affected, but any bone may be the seat of the disease. In advanced cases most bones suffer, leading to great deformity. The diagnosis is not easy when only one bone is affected.

Various treatments have been suggested, but none has proved of any value. I was prompted to write this paper by the excellent results obtained in four cases that have been under observation for nearly three years, but the number of cases is small, and the period of observation short, for a disease progressing so slowly. The complete disappearance of symptoms, and the marked return of the bones to normality, as shown by radiograms, has tempted me to take this step with a view to getting a greater number of patients treated by this method, and having my findings confirmed or otherwise.

The cases described illustrate well the difficulties of arriving at a correct diagnosis.

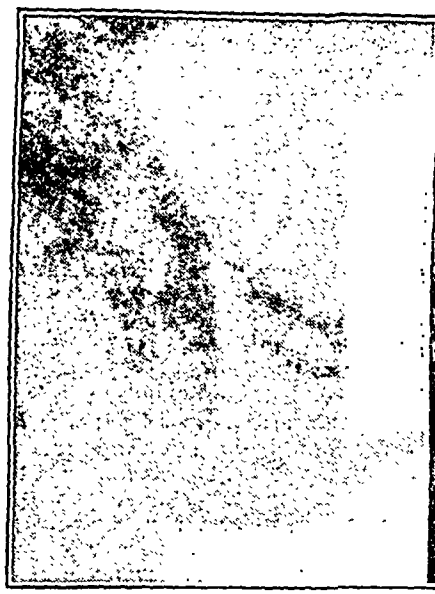


FIG. 1.

FIG. 2.

CASE I.

The patient was a man, aged 55. There was nothing of importance in his family or personal history until 1925, when he was knocked down by a motor cycle and severely bruised. In 1918, however, he had complained of aching in the right groin, and was advised to diet himself. The pain diminished, but did not disappear entirely. In the summer of 1927 severe pain was felt in the same region. Sleep became impossible without hypnotics, and he was unable to follow his occupation. The local doctor suspected appendicitis, and referred him to a consultant. The diagnosis was uncertain until an *x*-ray photograph (Fig. 1) was taken, which showed osteitis deformans affecting the ischium.

He was seen by me in December, 1927. He looked ill owing to the pain he had suffered, the sleepless nights, and the worry of losing his employment. He was put on general ultra-violet ray treatment three times a week; at the end of twelve sessions the pain was distinctly less, and after twenty-four doses he had practically lost it. There was a marked improvement in health, and he resumed his work. With the exception of short breaks he persevered with treatment until the beginning of 1929, when a pause was suggested. After a period of five weeks there was a slight return of the aching, and treatment was restarted twice a week, when the pain again disappeared. He has since maintained excellent health in spite of a sedentary occupation and long working hours. An *x*-ray photograph, taken ten months after the commencement of ultra-violet ray treatment (Fig. 2) shows a remarkable improvement in the condition of the bone.

CASE II.

An unmarried woman, aged 68, had previously been well, and there was nothing significant in her family history. In the summer of 1926 she bruised the right shin against a bath. In September of the same year aching started in the right leg, and she noticed a slight bowing. A bone-setter diagnosed arthritis, and advised exercises and diet, but the pain continued to get worse.

She was seen by me in January, 1928, when she had marked anterior bowing of the right tibia, and considerable enlargement of the diameter of the bone. A radiogram showed typical osteitis deformans, with great thinning of the compact bone. She was put on an ambulatory splint, taking the weight on the tuber ischii, in order to prevent a fracture, and a course of general ultra-violet irradiation three times a week was started. The tone of the muscles was maintained by a course of graduated faradic contractions. At the end of twenty treatments the pain had diminished considerably, and after three months she had lost all symptoms. An *x*-ray photograph showed regeneration of bone, and the calliper was discarded. This patient had been advised to have one-month courses of irradiation, with six-week intervals. There has been no return of symptoms, and she has maintained perfect health.

Two other cases, one in a woman, aged 54, suffering from osteitis deformans affecting the tibia, and the other in a man, aged 70, with Paget's disease affecting both femurs, have responded by disappearance of pain within three months of the commencement of treatment, and apparent arrest of the disease, as evidenced by regeneration of bone.

I much regret that the calcium content of the blood was not determined before and during the treatment; it might have thrown some light on this obscure condition.

All the cases were irradiated from a mercury vapour lamp. The area of skin exposed was increased gradually so as to raise the patients' tolerance to the rays, and the doses given were designed to produce the faintest erythema possible.

When the symptoms have disappeared it is important to impress upon the patients that treatment should not be discontinued for too long a period. This should not be difficult with a form of treatment which is not in the very least unpleasant, and is generally followed by a feeling of well-being.

PRIMARY CARCINOMA OF THE APPENDIX.

BY

HUGH REID, M.B., CH.B., F.R.C.S.,

HONORARY ASSISTANT SURGEON, ROYAL INFIRMARY, LIVERPOOL;

AND

HUGH SMITH, M.B., CH.B.,

HONORARY PATHOLOGIST TO THE EYE AND EAR INFIRMARY, LIVERPOOL; HONORARY PATHOLOGIST, BIRKENHEAD GENERAL HOSPITAL.

IN the last few years a considerable amount of literature in many languages has accumulated on this subject, but up to 1906 only 42 cases had been reported. By 1926 the number of recorded cases had reached 300, and last year Selinger of New York reported 34 new cases from the Post-Graduate Hospital.

Etiology.

Here there is scope for the many views as to the etiology of cancer in general. Primary carcinoma of the appendix has been reported by MacCarty and McGarth in a child of

5 years. This fact, together with the embryological and phylogenetic position of the appendix, lends force to the theory that it arises in displaced or embryonic remains; but when we ask why the displaced cells should take on malignant characteristics at this early age, we are met by the host of problems related to carcinoma in general. Again, the appendix and inflammation are closely related, and the most frequent age at which carcinoma of the appendix appears corresponds to that at which inflammation of the appendix appears. The oldest patient was aged 81 years, reported by Rogg in 1913. More cases have occurred in females than in males, but statistics here are rather confusing, because although appendicitis is acknowledged to be more frequent in males, the female abdomen is more frequently operated upon than the male abdomen, and more female appendices are sent for routine section.

The case under consideration was that of a small girl, aged 13 years, who for the previous six months had complained of occasional attacks of sharp pain in the abdomen. Recently the pain had become localized to the right iliac fossa, and was followed by nausea. The mother stated that the pains were becoming more severe and made the child cry out. The appetite was good, the bowels regular, and there was no loss of weight.

On examination the girl appeared quite healthy and well nourished. There was no anaemia, or any abnormal general features. Palpation of the abdomen detected some "guarding" of the muscles over the right iliac fossa, and there was distinct local tenderness on pressure. Per rectum nothing abnormal was detected. A diagnosis of subacute appendicitis was made, and operation decided upon.

On opening the abdomen the appendix was found lying quite free in the abdominal cavity, without adhesions. The base was thick, hard, and solid, as though a hard green pea had been inserted into it. The distal portion was slightly distended. The caecum appeared normal, and there were no enlarged mesenteric glands. The appendix was removed, together with a small cuff of the caecum, the stump infolded in the usual way, and the abdomen closed. On cutting into the nodule at the base of the appendix it was found to be very hard and solid, almost obliterating the appendix lumen.

The report on the microscopic section by one of us (H. S.) was as follows: "The sections made from the nodular appendix show a carcinoma which in places resembles the basal-celled type, and in others a scirrhous type. In most places the lining mucosal epithelium is intact, but in one place there is infiltration of the mucosa by malignant growth. The growth extends to the peritoneal surface. The stroma is mainly fibrous."

Diagnosis.

As in the case we are reporting, no one has yet made a diagnosis of primary carcinoma of the appendix before operation. It may be found post mortem, it may be found on routine microscopical examination of the appendix—which, indeed, is the reason for the increasing number of cases recently recorded—or it may be recognized when the abdomen is opened. The case presents the usual symptoms of a subacute or chronic appendicitis and clinically is diagnosed as such, or the appendix may be perforated by the growth, and symptoms of acute appendicitis ensue.

Statistics of the Mayo Clinic and other large clinics where great numbers of appendices are examined as a routine show the frequency of primary carcinoma to be under 1 per cent.

Pathology.

It has been denied that this condition is really a carcinoma, but that the tumour represents endothelial proliferation as a result of inflammation or displaced epithelial cells. Hertzler points out in support of this view that the usual round-cell infiltration is absent, and that the connective tissue retains its acidophilic properties. For this reason the name "cancroid" has been suggested. Fortunately, the condition is generally benign, but there are several records of metastases in the liver, the peritoneum, or the lymph nodes. Also, although the growth is generally confined to the mucous and submucous layers with a tendency to infiltrate the muscular layer, it is nearly always limited by the serosa. Different types of cells have been found. The spheroidal-celled type is most common, but, as one would expect, cuboidal, cylindrical, endothelial, and mixed types and colloid degeneration may all be represented.

Selinger, in his article in the *Annals of Surgery* (1929), quotes the latest word by P. Masson:

"Carcinoids result from proliferation of the intranervous argentaffin cells of the neurocoine type. They pile up in the nerve fibres, finally rupture their sheaths, and infiltrate the intestinal tissue of the mucosa and then that of the submucosa."

Conclusions.

Primary carcinoma of the appendix is not so rare as to constitute a pathological anomaly, but is becoming more and more widely recognized. Occurring as it may do in young children, it provides a further field for research and speculation on the origin and nature of cancer in general. Considerations of the phylogenetic and ontogenetic development of the appendix together with this pathological change may throw further light on the problem.

The general benignity of the growth, unless it occur at the base of the appendix or infiltrate the neighbouring structures, suggests that treatment should be limited to removal of the appendix without resection of the ileo-caecal region.

SYMMETRICAL GANGRENE COMPLICATING RHEUMATOID ARTHRITIS.

BY

RALPH BROOKE, M.S., F.R.C.S.,

HONORARY ASSISTANT SURGEON AND ORTHOPAEDIC SURGEON, ROYAL WEST SUSSEX HOSPITAL.

RAYNAUD'S disease has been reported from time to time as a complication of rheumatoid arthritis, giving rise to attacks of local syncope and asphyxia in the extremities, and loss of tissue, notably in the ears and the tips of the fingers. Llewelyn Jones mentions that in one advanced case in which Raynaud's symptoms developed, areas of skin over both heels underwent a necrotic change. Records of cases of symmetrical gangrene due to other causes are difficult to find, and it is for this reason that the following case was thought to be of interest.

A married woman, aged 32, with two children, stated that as a child she had always had cold hands and feet. Eight years previously she was first taken ill with an attack of acute rheumatism affecting both feet, the left ankle, both knees, and both hands and wrist-joints. The condition became gradually worse, treatment at Bath affording little relief. Six weeks before admission to hospital she noticed that her hands and feet were very cold and painful, and that the circulation was poor. Four weeks later she discovered that the right foot and the left hand were changing in colour, gradually becoming black; this change was accompanied by excruciating pain, more especially at night.

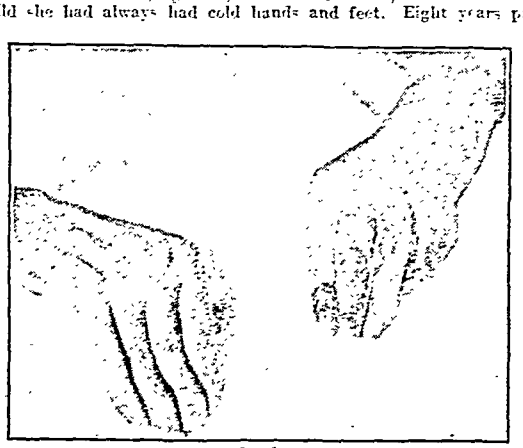

FIG. 1.

The patient was admitted into hospital on November 12th, 1929. She was pale and markedly wasted, and all four extremities showed advanced arthritic changes of the rheumatoid type. There was well-marked dry gangrene of the right foot affecting all the toes and extending proximally for two inches along the dorsum of the foot, with a well-marked line of demarcation; there was also gangrene of the left hand (see photograph, Fig. 1). The left foot

and right hand were blue, cold, and congested, but sensation in the limb was not affected. The ears were warm and of normal colour. The chest showed clinical signs of bilateral advanced active apical tuberculosis, which was confirmed by an *x*-ray examination; there was also evidence of myocardial degeneration. The Wassermann reaction was negative. The blood count was as follows: haemoglobin 58 per cent., red cells 3,500,000 per c.mm., white cells 15,000, colour index 0.8. No atypical cells were seen, and the urine was found to be normal.

Two days after the patient's admission the left foot became gangrenous, and a line of demarcation rapidly developed in the region of the mid-tarsal joint. Owing to the intense pain in the limb, operative measures were undertaken without delay. A peri-arterial femoral sympathectomy was performed in Hunter's canal,

FIG. 2.

and the femoral vein was also ligatured. At the operation the diameter of the femoral artery was found to be no larger than that of a slate pencil. Five days later the leg was amputated above the ankle-joint under local anaesthesia. Seven days later the right leg was amputated above the ankle, and the left hand at the wrist. The wounds healed rapidly, and the patient was discharged to her home two weeks later. So far there has been no recurrence of the gangrene.

Microscopical examination of the blood vessels in the amputated limbs showed the main artery with its lumen obliterated by an ante-mortem clot. There was also evidence of adhesions in the surrounding tissues, and of obliterating endarteritis in the small vessels.

The typical attacks of local syncope, pointing to Raynaud's disease as the cause of the gangrene, were absent in this particular instance. There is every reason to regard the cause as rather due to a toxic endarteritis, possibly rheumatic in origin or perhaps accentuated by the active tuberculosis, combined with thrombosis, the result of the sluggish circulation in a bed-ridden patient.

MEDICAL, SURGICAL, OBSTETRICAL.

THE STATIC TREATMENT OF ENLARGED PROSTATE.

The term "static electricity" applies to electricity at rest, of a high voltage stored up and held in a Leyden jar, or in the fields of a reposz machine. In 1750 Jallabert of Geneva published the first recorded on the medical uses of static electricity. He discovered as well as that static administrations increased the pulse rate and that the skin temperature of the patient. He also claimed that a static bath was valuable in cases of amenorrhoea, and that an increased secretion of sweat and urine was induced. Jallabert also demonstrated that paralysed muscles when treated by electrical sparks responded with a convulsive movement of individual muscles wherever the sparks were applied. This was the first demonstration that the static current induces "independent muscular contractions," independent of the nervo-muscular mechanism, a property which explains the peculiar efficiency of the static modalities in effecting tissue drainage with the removal of local stasis. Benjamin Franklin and John Wesley subsequently became advocates of the therapeutic use of static sparks. The Holtz and Topler-Holtz machines were not invented until 1865. These, and later the Wimshurst machine, made possible the production of currents in greater quantity and voltage than was possible with the friction machines.

To Dr. Morton of New York is due the credit of having discovered what are now known as the static induced and static wave currents. In conjunction with Dr. W. B. Snow much useful therapeutic work was carried out, especially in rheumatoid arthritis and other inflammatory conditions, and it was observed that removal of induration and accompanying swelling (tissue drainage), with the relief of pain, tenderness, and muscular tension, was effected with the static modalities. How is it that static electricity fills this unique role? It is because no other form of electricity is generated under anything like the same conditions as the static current, and electricity from no other source possesses to the same extent its unique qualities or characteristics, which are (1) high voltage relative to an infinitely small amperage, (2) the property of diffusion derived from the preceding qualities, (3) ionization of the air to these currents. Furthermore, the current is a constant current and a directional current of high potential, and produces its effects upon the muscular cells beneath skin and fat, whereas the low galvanic current is only effective when applied directly to muscular tissue—that is to say, static current produces cell contractions of the muscular and elastic tissues of the body independent of the neuro-muscular [illegible] we have a powerful remedy, safe and universal application, yet neglected.

The [illegible] of static wave current to diseased conditions is [illegible] but I propose here to deal with the treatment of [illegible] prostate, simple or post-gonorrhoeal. In treating an [illegible] prostate the method employed is as follows: [illegible] patient is placed upon an insulated couch, lying [illegible] side; a suitable rectal electrode connected with [illegible] is introduced into the rectum, in the media[illegible] machine in contact with the gland. The usual duration [illegible] and [illegible] is thirty minutes, the length of the spark-gap [illegible] treatment [illegible] increased as relief of the condition permits —that is, [illegible] ce increases.

I have often [illegible] during a course of treatment that sexual power [illegible] been increased, and in many cases restored. In [illegible] and epididymitis the relief is prompt. To explain these [illegible] results one may recall the action of the static wave current on the tissues: (1) increase in circulation; (2) contractile effect on the swollen infiltrated tissues, and on all muscular and elastic tissue in and around the gland. Briefly, massage with drainage and direct stimulation is obtained. Bearing in mind these properties, it will be seen how readily the swollen and enlarged prostate can be reduced, the symptoms relieved, and the patient restored to comfortable existence.

London, W. ROLF CREASY.

MULTIPLE ANEURYSMS.

THE following case of multiple aneurysms may be of interest.

On September 3rd, 1929, a man, aged about 60, with one leg, arrived at a boarding-house in this town. He complained of not feeling well, and retired early to bed, where he was found dead next morning.

I performed a post-mortem examination on September 5th. He was a well-built, muscular man. The left leg had been amputated through the thigh. On the inner side of the right thigh, just above the knee, was a large, hard swelling. The peritoneal cavity was full of blood, and there was much recent blood clot in the retroperitoneal tissues. There was an aneurysm just above the bifurcation of the abdominal aorta, roughly spherical in shape, and about 2½ inches in diameter. This had ruptured through a slit 1 inch long in the anterior surface. The swelling on the right thigh proved to be an aneurysm of the femoral and popliteal arteries, and was about 6 inches long by 3 inches in diameter, and filled with laminated blood clot. No other aneurysms were found. The heart was enlarged (weight 14 oz.), and there were atheromatous patches on the aorta, but no valvular lesions.

Dr Henderson of Bayswater, who had attended the man during life, tells me that the left leg was amputated some years ago for a femoral aneurysm which was causing gangrene of the foot. The aneurysm in the right thigh had recently consolidated and ceased to pulsate. The man denied having had syphilis.

Reports of Societies.

SPINAL ANAESTHESIA.

At a meeting of the Section of Anaesthetics of the Royal Society of Medicine, on March 7th, with Mr. R. E. APPERLY in the chair, Mr. CHARLES DONALD read a paper on spinal analgesia with spinocain, and Dr. HOWARD JONES a paper on percain with special reference to high thoracic nerve-root block.

Mr. Donald referred to the claims made by Dr. Pitkin of New Jersey for spinocain as an anaesthetic—namely, that with a minimum of toxicity the preparation gave absolute control of analgesia, no fall of blood pressure, and an absence of post-operative complications. The solution contained novocain, of which the toxicity was certainly not high; strychnine, which was introduced to maintain the blood pressure; alcohol to reduce the specific gravity of the mixture below that of cerebro-spinal fluid; and a viscous starch solution to delay the rate of absorption. In theory, the solution should behave like the bubble in a spirit level when injected, and its effects should be controllable by the position of the patient, but in practice it had been wayward. Less analgesia resulted from an injection of a dose of spinocain than from the injection alone of an amount of novocain equal to that included in the dose; this indicated a slower rate of absorption of spinocain. With an injection of 2 c.cm. results varied; 3 c.cm. gave analgesia to the transverse nipple line and 3.5 c.cm. to the level of the second rib. In the spinal canal spinocain did not behave like a light fluid, so that he had given up tilting the patient until analgesia was obtained; relaxation was often disappointing. He had found that 3 c.cm. gave analgesia in fifteen to twenty minutes, whether expanded with cerebro-spinal fluid first or not: it was not, therefore, any more controllable than novocain. He had never had symptoms of respiratory paralysis, though analgesia had reached the second rib in twenty-four cases. More than half the cases gave the same results with equal doses of spinocain, whether expanded or unexpanded. Old persons, persons of full habit, and those who were seriously ill were more quickly affected than others, and required a smaller dose. Ephedrine was used with a local anaesthetic before insertion of the needle; this was supposed, like the strychnine, to help to maintain the blood pressure. In practice the blood pressure always fell a little, though only about one-third, or less, of his cases had shown a fall of more than 20 mm. of mercury. The use of intrathecal strychnine had often been tried but invariably discarded. The effects of ephedrine were not conclusive. As to complications, there had rarely been anxiety while the patient was on the table; one had died during operation, and three others within a few hours, but all these had been *in extremis*. There had been no cases of post-operative pneumonia, paraplegia, or ocular palsies. Two patients had developed paralytic ileus, but it was probable that they would have done so whatever the anaesthetic. Most of his patients had been constipated for a day or two after operation. Spinocain could be used with safety for 23 per cent. of operations below the diaphragm; it could be pushed to include more than the lower abdominal field, but in the upper abdomen its effects were variable. It had not justified the major claims of Pitkin—namely, complete controllability and maintenance of blood pressure. The only advantage it showed over novocain was its slower rate of absorption.

Dr. HOWARD JONES, before beginning his communication on percain, offered a criticism of Pitkin's theory of the action of spinocain. It was useless to put alcohol in the solution in order to reduce the specific gravity, since, as soon as mixing occurred, the heavier constituents would react to gravity. The ascent of the anaesthesia and its disappearance from above downwards suggested gravitational diffusion. Further, any method which depended on the withdrawal of a specific quantity of cerebro-spinal fluid was unreliable. Turning to percain, he would remind his hearers that the specific gravity of cerebro-spinal fluid varied between 1003 and 1010. Percain could be used in dilutions of 1 in 1,000, 1 in 2,000, 1 in 1,500, and, in small doses, in dilutions of 1 in 500 or even less. The drug was so potent that its weight in solution added practically nothing to the specific gravity of the solvent. It was used in normal saline, and in saline of strengths between 0.5 and 0.9 per cent.; and the solution so formed might be hyperbaric, isobaric, or hypobaric to the cerebro-spinal fluid. With hyperbaric solutions there was a danger of spread by gravity if the patient was placed too early in the Trendelenburg position; time should be allowed for the absorption of sodium chloride to reduce the specific gravity of the solution, or else hypobaric solutions only should be used. A solution with a specific gravity of 1005 to 1006 was usually hypobaric; the dorsal roots must be well soaked after the injection, by placing the patient on his face. If this was omitted there was danger of producing an anterior root block only, with paralysis of muscles and no analgesia. Solutions should be fresh, and used at body temperature. The duration of anaesthesia was proportional to the concentration of percain; a concentration of 1 in 2,000 gave analgesia for three-quarters of an hour, and a concentration of 1 in 1,000 gave analgesia for two hours or more; 15 c.cm. of 1 in 1,000 was usually sufficient for appendicectomy. The injection was made without withdrawal of fluid; as soon as a pressure resistance was felt the injection was made slowly, 2 c.cm. at a time. Usually the patient did not complain of headache. The fall of blood pressure was not as severe with percain as with novocain or stovaine, and the pulse was but little affected. The drug was relatively non-toxic, owing to the high dilutions in which it was used and to its slow absorption. Vomiting often occurred during high operations owing to vagal reflexes. It was advisable to have the thorax slightly tilted downwards to avoid any chance of vasomotor paralysis; phrenic paralysis was unlikely to occur with the doses employed. Breathing might become shallow and cease when the intercostal muscles were paralysed, since diaphragmatic breathing led to anoxaemia and depression of the vasomotor centre: this in turn gave rise to shallower breathing, and a vicious circle was established. The treatment was to give gas and oxygen, allowing rebreathing to occur; the carbon dioxide generated by the patient stimulated the respiratory centre and restored deep inspiration. Failures with percain were due to miscalculation, or to anterior root block preponderance, due to insufficient soaking of the posterior roots in the ventral position, or to the use of hyperbaric solutions, which gave rise to root block in the ventral position. Vomiting and headache occurred sometimes as after-effects, but were usually not severe. At Charing Cross Hospital ephedrine had been found to act as a cure for spinal headache. Percain was particularly valuable on account of the small excess of its dose; 7½ mg. of percain had a longer effect than 150 mg. of novocain.

Mr. PETER DANIEL said that he had found percain to be an excellent anaesthetic from the point of view of the surgeon. He thought the tendency to vomiting, due to vagal reflexes, might be controlled by the application of a swab soaked in percain to the oesophageal orifice during operation.

Mr. NORMAN C. LAKE said that he had produced the vagal inhibition suggested by Mr. Daniel by the injection of percain into both sides of the oesophagus, with good results. He had found the after-effects of percain to be mild, and had used it for regional anaesthesia in removing a pituitary tumour, with no other anaesthetic.

Mr. C. JENNINGS MARSHALL said that he had found percain to be an invaluable form of spinal anaesthesia. Relaxation was complete under its influence. Mr. A. G. ALLEN said he had had very good results with percain as a local anaesthetic for dental work. Mr. E. FALKNER HILL said that where spinocain was used, though analgesia lasting one and a half hours could not be guaranteed, it was often obtained. Vocal control was an essential if spinal anaesthesia was to be perfected. LIEUT.-COLONEL G. REES-MOGG mentioned the possibility of urgency of micturition after spinal anaesthesia. Dr. T. H. SELLORS said that he had used percain as a regional anaesthetic, with good results; and that it was also useful to anaesthetize the urethra in cystoscopy, and as a dressing for burns and raw surfaces.

Mr. FRANKIS EVANS described three cases in which he had used percain as a spinal anaesthetic with success. Mr. DICKSON WRIGHT described two cases in which severe cyanosis and delirium had occurred in patients after the use of percain. Mr. R. E. APPERLY said that he had used percain as a regional anaesthetic with good results.

Mr. DONALD, in replying, said that he held no brief for spinocain, but that the viscous medium helped to cause slow absorption. It was often not the anaesthetic, but the anaesthetist, who was responsible for good results in spinal anaesthesia.

Dr. HOWARD JONES said that headache and vomiting should not be too readily attributed to the anaesthetic. These symptoms might follow simple lumbar puncture. The same argument applied to the development of such a symptom as cyanosis; causes other than the anaesthetic might be found.

MALIGNANT DISEASE OF THE EAR.

AT a meeting of the Section of Otology of the Royal Society of Medicine, on March 7th, with Mr. M. W. MOLLISON in the chair, several papers were read on malignant disease of the ear, and cases and specimens were demonstrated.

Mr. G. J. JENKINS described three cases illustrating a very similar syndrome. In each instance there was a history of severe injury to the head occurring some years before the development of the disease, which was of slow growth and low malignancy. The first patient, who came to King's College Hospital in 1926 for severe pain and profuse haemorrhage in the left ear, had a history in 1916 of a blow on the head, though not such as to produce unconsciousness. The trauma was followed by twitching of the left side of the face and paralysis, but eventually all signs cleared up except deafness in one ear. On examination ten years later a polypus was found blocking the meatus. The treatment comprised operation and radium therapy; in this and in the other cases success was attained. The æ-ray appearance in all three cases was similar. The injury to the head suggested that the cyst was due in some way to injured blood vessels, but a pathological examination revealed the characteristics of sarcoma. In these cases there was a curious conical or triangular infiltration of the membrane.

Mr. E. BROUGHTON-BARNES dealt with the early diagnosis of carcinoma of the ear; his own experience was limited to three cases, but he had collected a number of others from the literature. In eight out of ten cases the condition was squamous-celled epithelioma; in one it was squamous adenocarcinoma, and in the remaining case rodent ulcer. Most of the patients had had otorrhoea for some years. Four symptoms occurred with special frequency—namely, pain, facial paralysis, granulations of the meatus, and tendency to bleeding. When epithelioma arose in the meatus the patients sought advice early on account of the pain, and there was an opportunity for early diagnosis; it was otherwise when the growth was in the mastoid. In one of the speaker's cases, a woman aged 76, there was early growth in the meatus; here there was prompt recognition by section, and a good result followed very simple radium treatment, a radium needle being worn in the meatus for ten days. The ulcers disappeared completely, and two and a half years afterwards the patient was perfectly well, the hearing in the affected ear being at least as good as in the other.

Mr. HERBERT TILLEY exhibited a case of malignant disease of the right external auditory meatus in a man who had complained of stabbing pain in the right ear and occasional but slight discharge. Examination revealed a pale excavating ulcer on the deep antero-inferior wall of the right meatus. The granulations were hard and resisting when probed, but nevertheless bled freely. Sir J. DUNDAS-GRANT demonstrated microscopical sections from a case of epithelioma of the external auditory meatus, in which the probe had revealed a remarkably extensive area of bare bone on the posterior wall of the meatus. Mr. T. JEFFERSON FAULDER exhibited a specimen of malignant disease of the right ear, and Mr. GILBERT CHUBB and Mr. F. C. ORMEROD showed a patient who had had a carcinoma in the external acoustic meatus; this had been treated by radium, and there had been no recurrence of growth or pain for more than a year. Five needles, each containing 1.3 mg. radium, had been inserted into the wall of the meatus on the superior, posterior, and inferior aspects, and a total dose of 1,404 mg. hours had been given. The growth and pain disappeared in about a month after the removal of the radium.

Mr. A. R. TWEEDIE asked whether the cases reported by Mr. Jenkins could be definitely said to be malignant. The question of trauma was an important factor, and the fact that the character and the microscopical appearance were cystic rather suggested a vascular lesion. In a slowly progressive condition such as this, one rather hesitated to advise an operation which was certainly going to mean a good deal of mutilation and involve a long time in recovery. Dr. DAN MCKENZIE said that an interesting point was the occurrence of facial paralysis in connexion with the development of the growth, thus offering one more possibility to be borne in mind in a case of facial paralysis. The method of treatment in this disease would vary according to its type and situation. In the deep cases illustrated by Mr. Jenkins, where the malignancy was mild, radium offered itself as the remedy. When epithelioma occurred in isolated and removable points such as the pinna, the speaker thought diathermy was indicated rather than radium. If the disease was in and about the bone in the mastoid he did not think that diathermy was serviceable; the whole of the growth could not be removed by that means, and its utilization did not seem to confer any advantage over ordinary curetting. Mr. JENKINS, in reply, said that the cases were of definite though of low-grade malignancy. They were of slow growth, one of them lasting for ten years, and another for six. This was not one of the growths which gradually infiltrated the tissue; it projected itself forward by mere invasion, pushing other tissues out of the way. He did not think there was any argument against early operative procedure; such procedure was not dangerous.

A paper by Professor J. S. FRASER was read in his absence, containing particulars of eleven cases of malignant disease of the external auditory meatus and the middle ear. Among 646 cases seen in private practice from 1906 to 1929 in which the external acoustic meatus was affected, he had had three cases of malignant disease of the external meatus; in the statistical tables of the Royal Infirmary, Edinburgh, out of 6,605 cases of affection of external ear and meatus there had been 13 of malignant disease.

THE PHYSIOLOGY OF INSECTS AND HUMAN DISEASE.

THE digestive and respiratory systems of insects were discussed in a lecture given by Dr. V. B. WIGGLESWORTH, of the London School of Hygiene and Tropical Medicine, to the Royal Society of Tropical Medicine and Hygiene on February 20th.

Dr. Wigglesworth pointed out that such a study was important from the aspect of human disease when it was remembered that the digestive tract of the insect often formed the chief culture medium of the pathogenic organism during its sojourn in the intermediate host, and that it was frequently through the respiratory system that insects proved most vulnerable to poisonous agents for their extermination. He described in detail the physiology of digestion in an omnivorous insect such as the cockroach, and then compared it with that of an insect which had become strictly adapted to a diet of blood—namely, the tsetse-fly. He said that so far as present knowledge went the only special adaptations in the tsetse-fly to an exclusive diet of blood were the loss of those enzymes which acted upon carbohydrates, a great increase in the quantity of proteolytic enzymes, and the acquisition of factors affecting the coagulation of the blood. Whether the rapid absorption and excretion of liquid from the blood—which occurred in the tsetse-fly as in most blood-sucking insects—was asso-

ciated with any special changes in the absorptive properties of the mid-gut, had not yet been determined. But the rapid removal of fluid presented many interesting problems in both absorption and excretion, the solution of which in insects might well prove of great importance in physiology generally. The gut of the tsetse-fly contained some greatly hypertrophied cells, whose cytoplasm was stuffed with little rod-shaped but highly pleomorphic micro-organisms resembling large bacteria. Whether these "bacteroids," as they were called, were true symbionts, as had been argued, could not be regarded as proved at the present time, but their constant occurrence in cells specially prepared to receive them, and their hereditary transmission, suggested that they did in fact contribute something of value to the economy of their host. Similar organisms occurred in other blood-sucking insects—the louse, for example—but they were absent from the flea and the mosquito. Possibly they manufactured for their hosts some accessory growth factor comparable to the vitamins necessary for mammalian growth. With regard to the respiratory system, Dr. Wigglesworth advanced a theory, complementing the work of Krogh, according to which the extent of air along the terminal tracheoles was controlled by the osmotic pressure of the tissue fluids; and since the osmotic pressure increased in active tissues, the supply of air was greatest where it was most needed. He described experiments on mosquito larvae by which this theory was substantiated, and related these findings with the effect of oil as a larvicidal agent.

In the course of some discussion after the lecture Colonel F. P. MACKIE, I.M.S., mentioned that in work in Uganda it had been found that certain trypanosomes could infect parts of the alimentary canal of the host to the exclusion of other parts. Some passed into the salivary glands, others developed only in the proboscis. In malaria, again, it had always seemed inexplicable to him why in certain species of mosquito the malarial parasite should undergo a partial development and then cease; and, again, why in some species, which had never been incriminated as carriers in the field, transmission should be obtained in the laboratory. He believed the solution to be in the physiological reactions of the insects concerned. Certain species of phlebotomus, again, were capable of providing a suitable environment for the parasite of kala-azar, and others had no such power. Most important of all was the question of plague, the distribution of which in the East had been supposed to depend largely upon the distribution of *Pulex cheopis*; but experiments in his laboratory on a large scale had shown that *P. brasiliensis* and other species were equally valid as plague carriers.

Dr. C. M. WENYON referred to some recent work in Russia whereby species of mosquito other than anopheles appeared to harbour the malarial parasite in the initial stages of its development; but development was stayed, apparently, by something in the tissue fluids of the insect.

RADIUM TREATMENT OF CANCER.

AT a meeting of the Liverpool Medical Institution, held on February 13th, Mr. C. THURSTAN HOLLAND and Dr. J. M. WOODBURN MORISON of Edinburgh opened a discussion on radium in the treatment of malignant disease.

Mr. THURSTAN HOLLAND said, in his opening remarks, that radium never had been, and never would be, "the cure for cancer": like the knife, diathermy, and so forth, it was a local remedy, and no local attack could ever be entirely successful. In criticizing very severely the methods and propaganda for raising money for radium, he said that these had led the general public to believe that, given enough radium, cancer need no longer be feared. Statistics purporting to contrast the results of radium treatment with surgical treatment were unreliable: thus, the five-year "cure" was not necessarily a "cure"; in the large majority of cases the removal of a tumour was not enough; the condition was already generalized, and it was merely a matter of time before some kind of protection gave way and recurrence or metastases followed. Each year considerably over half the cancer mortality was from disease of the gastro-intestinal tract and its appendages, and these organs, said Mr. Holland, could not be a very hopeful field for radium treatment.

Dr. J. M. W. MORISON referred to the excellent pioneer work of the radium institutes of London and Manchester, and of the various research organizations in this country. Outlining the policy of the National Radium Commission, he said that the Commission, far from imagining that the problem of the use of radium in the treatment of cancer had been settled, believed that it called for careful research under the guidance of the faculties of medicine of the universities, in association with the great teaching hospitals. In the great Continental centres the trend in radium therapy was to avoid, wherever possible, the direct introduction within the tissues of tubes and needles, the line of advance being the development of the surface applicator, so designed that the distribution of tubes and needles on the outer surface gave what was, for all practical purposes, a uniform irradiation on the skin surface. The work of Murdoch and Stahel at l'Hôpital Burgmann in Brussels was a genuine advance. Radium therapy was still in the experimental stage, but the results, he believed, justified its use and the promotion of further research.

Mr. G. C. E. SIMPSON suggested that the openers had taken too pessimistic a view. Surgeons experienced in the diagnosis and treatment of cancer should not be superseded by a new class of specialist—the radiological expert on cancer. While in every centre he should have at his disposal the advice of such experts, the surgeon, in present circumstances, was justified in using radium if he had made himself familiar with the treatment adopted and the results obtained in great surgical clinics which had advanced radium treatment in recent years. In operable cases such treatment had advantages over mutilating operations, and in some sites—for example, the floor of the mouth—radical surgery of cancer was highly dangerous, and generally ineffective, while radium treatment, in many cases, produced apparent cure.

Mr. F. STRONG HEANEY agreed with Mr. Thurstan Holland that radium was not a "cure" for cancer, but surgeons and gynaecologists, he said, had not really held exaggerated ideas about its value. Appeals for funds were made by laymen, and often worded without reference to medical men; it was regrettable that exaggerated claims had been made, but the medical profession itself was fully aware of the limitations of this very valuable weapon for treating cancer. Objection had been taken to the so-called five years' standard of non-recurrence, but the only way of comparing results was by adopting some arbitrary period. Cases, he held, must be selected by persons in a position to judge the possibilities of the alternative lines of treatment. The collaboration of the radiologist and the physicist was indispensable: whether in the hands of surgeons or radiologists, methods were still largely empirical. Radium would continue to be preferred to deep therapy until the latter gave better results.

Dr. RAWDON SMITH said that, while certain of the methods for raising money were to be deprecated, he hoped that the public would subscribe for radium in Liverpool, where both research work and radiotherapy were behind-hand.

Mr. PHILIP HAWE said that treatment by the radium bomb was only justifiable in the most expert hands: its dangers were so great, and its value so doubtful, that it was unlikely to come into more general use. He was much impressed during a visit to Brussels by the value of combined methods, involving the use of radium, surgery, and *x* rays. For example, carcinoma of the rectum was probably best dealt with by a preliminary colostomy, followed, after eight days, by an application of radium, and then, in two months, by a perineal resection. Operable breast cases were dealt with by a preliminary course of *x*-ray therapy, followed by operation on the usual lines, and, finally, by another course of *x* rays. For treatment of superficial recurrences and inoperable cases radium was used, and for deep recurrences *x* rays. With extensive radiation regular blood examination was very important, a leucopenia being a danger signal.

Professor W. J. DILLING said that, from personal knowledge of the results obtained at the Radium Institute in Paris, he was convinced that further supplies of radium

were necessary in Liverpool in order that patients might not be denied the benefit that this therapeutic agent afforded in certain types of malignant disease. In Liverpool the ideal system for the effective utilization of radium was the establishment, under the supervision of the university, of a radium institute, where a directing medical officer, specially trained in the physics and modern technique of both *x*-ray and radium therapy, could advise surgeons about dosage and methods, and organize research with a view to improving technique and the results of treatment. The decision of the Radium Commission to lend radium to only one hospital in an area was not, in his opinion, likely to facilitate the use of this therapeutic agent in the most deserving and appropriate cases.

Dr. C. O. STALLYBRASS discussed the best way of securing the co-operation of the surgeon and the radiologist, and the question of training radiologists in the treatment of cancer.

Mr. FRANK JEANS said that neither Mr. Holland nor Dr. Morison was a pessimist; treatment, whether by radium or by surgery, might be productive of good or bad results; radium had not yet supplanted surgery. Naturally patients preferred radium, but the fact had to be faced that there was a great deal of cancer and very little radium, and surgeons had to operate nearly as much as ever before. Extravagant claims had been made for radium, perhaps on the assumption that the public would not subscribe for research, but would for a promise of cure.

Protrusion of the Mandible.

Mr. G. C. E. SIMPSON and Mr. H. G. WATKIN made a joint communication on a case of protrusion of the mandible in a man of 28. The lower teeth were 19 mm. in front of the upper, and the man was unable to eat well, and ashamed to eat in public. Mr. Simpson said the condition was in some cases congenital, and in others caused by finger-sucking, or early loss of temporary incisors, whereby the lower teeth got too far forward, etc. Once started it tended, unless checked, to increase from mechanical causes, and dental measures were most valuable before the loss of the deciduous molars. Angle and Whipple's operation of dividing the mandible on both sides, at about the level of the premolar teeth, was mentioned, and the results obtained on some of the deformities by this method were shown; but there were objections to it: first, the injury to the inferior dental nerve in the canal, and its effect on the front teeth, and, secondly, the probability of sepsis. Bruhn of Düsseldorf (as a result of co-operation of dental surgeon and surgeon in military orthopaedic surgery) relieved the condition by resecting the mandible below the notch, but above the inferior dental foramen, by a subcutaneous osteotomy, and this operation had also been performed by Babcock in Philadelphia. This method was chosen, and Mr. Watkin first fitted cap splints to the jaws, packing the splint to lever the jaw into the best position, as studied on models of the patient's bite, and the osteotomy was performed. After six weeks in the splints it was found that the upper posterior molars locked the bite, and that the incisors did not meet. After extraction of these teeth, and grinding down of some posterior teeth which had never met and been worn to the pattern of their opponents, the patient was left with sixteen teeth in good occlusion. The patient was now able to eat satisfactorily. Photographs and models were shown, and emphasis was laid on the advantage of the co-operation, from the start, of the surgeon and dental surgeon in the treatment of deformities and fractures of the jaws.

SPINAL CORD TUMOUR.

AT a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, held in the Royal College of Physicians on January 24th, with the president, Mr. R. ATKINSON STONEY, in the chair, Mr. C. J. MACAULEY read a paper on two cases of spinal cord tumour, and showed lantern slides.

The first case was that of a woman, aged 47, who began to suffer from weakness in the legs about six months before her admission to hospital. This progressed steadily until she was unable to walk, and for the past month she had been confined to bed. She had suffered from troublesome twitchings in both legs, but never had any pain; there was no sphincter disturbance. On examination, both legs were paralysed in flexion, with spasticity, increased knee-jerks, and ankle clonus. There was considerable sensory disturbance below the fifth intercostal space, on both sides. A radiogram of the spine failed to show any evidence of disease, and the Wassermann test was negative. The fluid withdrawn by lumbar puncture was yellow in colour, and showed a marked increase in globulin. The Queckenstedt phenomenon was present, an anomalous finding which may have been due either to an error in technique (the patient not having been warned against straining) or to the presence of a partial block. Lipiodol was injected into the subarachnoid space by cisterna puncture, and the radiogram showed arrest at the level of the third dorsal vertebra. Operation was carried out under ether anaesthesia, and a tumour was found at the exact level indicated by the radiogram. It was removed without difficulty. The patient stood the operation well, but developed acute respiratory trouble and died the next day. The tumour on section proved to be a fibromyxoma.

The second case, in a woman aged 35, whose illness began three months prior to admission, ultimately developed into complete spastic paraplegia. The patient gave no history of pain, but there was marked sensory disturbance in the limbs. The Wassermann test was negative. The cerebro-spinal fluid showed a marked increase in globulin, but without xanthochromia. The spinal pressure was not affected by compression of the jugular veins, but was markedly raised when the patient strained forcibly. Lipiodol injected by cistern puncture was arrested opposite the upper border of the third dorsal vertebra. At operation, carried out under local anaesthesia (except in its final stage), a tumour, reddish, soft, vascular, and adherent, was found at the level indicated by the radiograms. It was removed piecemeal, but apparently completely. There was much difficulty in separating the tumour from the cord, and considerable oozing. The patient made a good recovery from the operation, and after some weeks showed slight evidence of return of function. This improvement was not maintained, and at the time of writing the patient was still bed-ridden. The tumour, on section, proved to be a psammoma.

The PRESIDENT said that he had recently seen Dr. de Martel operate on a case of spinal cord tumour under local anaesthesia. There was apparently a distinct amount of pain and discomfort, but during the operation the patient was in the sitting position. This position was of great advantage, and to render possible its adoption local anaesthesia was necessary.

Dr. E. T. FREEMAN demonstrated a manometer for measuring the pressure of the cerebro-spinal fluid. Dr. CYRIL MURPHY drew attention to the fact that in the first case the cells in the fluid were 2,000 per c.mm., while in the second case they were only 4 per c.mm. Purves-Stewart had stated that deep tumours showed little pleocytosis, while in superficial ones the cells were greatly increased.

Dr. V. M. SYNGE said that if xanthochromia was present it was, he believed, positive evidence of spinal cord tumour, and that as a rule there was a great deal of globulin but no increase of cells.

Mr. A. A. MCCONNELL suggested that increase of girdle pain on coughing or on compressing the veins was an important sign of spinal block. He was interested to notice that lipiodol had been used, having regard to the fact that a good deal had recently been written about the dangers of its use, but in these cases it had apparently been very successful.

Sir WILLIAM WHEELER said he was struck with the usefulness of lipiodol in the cases described by Mr. MacAuley. He drew attention to the fact that this method was discouraged by some authorities, but these authorities had unusual facilities for expert neurological examinations. He mentioned a recent case with symptoms of spinal cord tumour in which pain was absent from start to finish. There was little or no sensory disturbance in the legs, but complete paralysis. The cases mentioned demonstrated the fact that root pain, though an important symptom, is not always present. He referred to an instructive paper by Adson. Thirty-five cases are mentioned in which laminectomy revealed no tumour. In his own case, although the lesion was localized by expert neurologists, no tumour was found at operation.

Mr. MACAULEY, in replying, said that in the second case it was impossible to get a strict line of demarcation. He thought that the importance of localizing the tumour was so great that, whatever pain was suffered after lipiodol injection, it was worth it.

Transplantation of External Biliary Fistula.

Mr. F. GILL read a paper on transplantation of external biliary fistula, and showed lantern slides.

Reviewing the literature of the subject, the lecturer said that in the *Collected Papers of the Mayo Clinic*, 1923,

Walters reported a case where this operation was successfully carried out. Recent reports of successful transplantation of a fistulous tract into the stomach or duodenum by Masson, St. John, Lahey, and Lilienthal had served as a stimulus to the use of this method. The procedure appeared to be ideal when dealing with cases of stricture of the common and hepatic ducts, in which an insufficient amount of duct remained below the liver to permit anastomosis to the duodenum or stomach: also in cases where extensive adhesions were present. Mr. Gill's own case, in a patient whose common hepatic duct was wounded during cholecystectomy, was as follows:

A married woman, aged 55, was admitted to Sir Patrick Dun's Hospital on June 2nd, 1929, complaining of pain in the upper part of the abdomen, shooting round to the back. The history was one of typical biliary colic. The patient suffered from flatulence and dyspepsia; there was tenderness and rigidity in the right hypochondrium, and slight jaundice.

At the operation on June 7th, 1929, the gall-bladder was found to be atrophic and to contain many stones. It was fixed by numerous adhesions to the duodenum and omentum; the junction of the cystic with the common hepatic duct was difficult to expose. The gall-bladder was removed. On examining the region of the cystic duct it was found that there were two openings—the cystic duct stump which was held in the clip, and above this the common hepatic duct, which was cut into near its termination. An attempt was made to close the opening in the common hepatic duct by interrupted sutures, and a drainage tube was placed down to the stump of the cystic duct. Bile began to flow freely a few days later. The amount varied; at times, when the discharge was slight, the motions were normal in colour, and when the discharge was increased the motions were clay-coloured. The amount of bile became less and less, and the tube was removed. The patient was discharged from hospital on July 27th, but the fistula persisted, and the amount of bile coming from it increased.

She was readmitted on October 31st, having lost 20 lb. in weight in six months. It was decided to transplant the biliary fistula into the duodenum or stomach, as great difficulty was anticipated in carrying out any other plastic operation with the extensive adhesions that were certain to be present.

The fistulous tract was transplanted into the pyloric portion of the stomach; the duodenum was firmly bound down by adhesions, and no attempt was made to separate them. The wound is now healed, the stools are normal, and the patient feels well and is putting on weight. From this case Mr. Gill was convinced of the ease with which a coned-out fistula could be transplanted. The only precaution necessary was that the external fistula should have been present long enough, so that it could be coned out as a well-established tract, and left attached to the liver.

The PRESIDENT suggested the possibility that after a time the fistula might contract. He asked if the cases mentioned by Mr. Gill had been recently operated on. Mr. A. A. MCCONNELL said that in some cases adhesions might be met with, and then the procedure might not be as simple as it looked on the lantern slides.

Mr. GILL, in replying, said that one of the cases he mentioned had been operated on two years ago, and the other about five years ago. No stricture had formed in either of these cases. He had found the operation very easy, and, by keeping the tube in position, had kept well away from the tract.

Hydatid Cyst of Liver.

Mr. ARTHUR CHANCE showed a specimen of hydatid cyst of the liver.

The patient, a woman aged 35, was seen on December 20th, 1929; she then had a very large abdominal tumour. Two months previously she had had an attack of severe epigastric pain and vomiting, lasting four days. Six days later she noticed a lump in her abdomen, which gradually enlarged, and on December 10th she became jaundiced. The tumour was situated in the middle line; it was rounded and immovable, and a very distinct thrill could be felt. Mr. Chance diagnosed pancreatic cyst, and *x*-ray examination showed that the stomach was very much pulled down, with an obvious filling defect in the lesser curvature. At operation a cyst was found, with a very thick and vascular wall. An incision was made into the cyst, and a large quantity of fluid came away, containing a number of small bladders, indicating its hydatid nature. A drainage tube was inserted, and enormous quantities of fluid poured out for six days.

It was stated that the best thing to do in these cases was to inject into the cyst some pure formalin. The disadvantage of drainage was that sometimes the cases continued to drain for months or even years. Dealing with the possible source of the infection, Mr. Chance said that the patient had always lived in France, except during the last two years, when she had lived in London. She had lived in a house where a dog was kept, and was fond of uncooked vegetables.

Reviews.

OPHTHALMOLOGY.

A TEXTBOOK of small dimensions suitable for the student on *The Pathology of the Eye*[1] certainly deserves a place in ophthalmological literature; a very readable handbook of this nature has lately appeared from the pen of Dr. J. S. FRIEDENWALD of Johns Hopkins University, the substance of which is based on the author's course of lectures at that institution. The book is a good one, not the least of its virtues being the manner of its writing: this is good throughout, and in parts excellent. In the main the teaching is sound, especially on such difficult and dangerous ground as focal infections and tuberculous infections of the eye. The author is undoubtedly right in considering that in this country and America the influence of septic foci is stressed with more promiscuity than reason. Why, he asks, do these organisms not cause infective lesions in the lungs whither they must travel first, and where they have a much greater opportunity of gaining a nidus if they are pathogenic? Not the least interesting parts of the book refer to the author's own observations; these are numerous and touch on many subjects; but, unfortunately, in a book of this size the space allotted by necessity to them is smaller than would allow us to appreciate or criticize adequately those of them which are not yet published elsewhere. His work on cataract leads him to support the theory, already advanced in Germany, that the main factor at fault is the permeability of the lens capsule: and on glaucoma, that it is due to an acute vascular crisis brought about by capillary dilatation. He has also made interesting observations on the retinal vessels in arterio-sclerosis, on the nature of keratitic precipitates, on the pathology of subacute panophthalmitis, and on the ocular lesions of foetal syphilis. There are, however, some points to which attention may be drawn. Few would agree that the mere loss of the blinking reflex is adequate to explain the phenomena which may be included under the term "neuroparalytic keratitis"; or that colobomata "involving the iris, choroid, or optic disc" are due to "a delayed atresia of the blood vessels, which in the embryo connect the ciliary with the hyaloid vascular system." This explanation forms the basis of one theory to account for colobomatous defects in the anterior part of the optic cup, but can hardly be applicable by any stretch of imagination to colobomata in the region of the optic nerve. Again, it may be questioned whether local venous engorgement is responsible for the exophthalmos of hyperthyroidism. Moreover, the painful inflammation which occurs after short-waved light is not essentially a conjunctivitis, but it derives its characteristics and its subjective symptoms from damage to the corneal epithelium, and is essentially a keratitis. The mechanism of papilloedema is said to be due to a lack of balance between the pressure inside the eye and that in the subarachnoid space, involving an obstruction to the outflow of the perivascular lymphatic channels; increased venous pressure is ruled out owing to its absence in thrombosis of the cavernous sinus, a deduction which takes no account of the venous anastomoses in the posterior part of the orbit. In the discussion of herpes zoster ophthalmicus the rare oculomotor paresis and optic atrophy are mentioned as complications, while the commoner accompaniments, as irido-cyclitis, are omitted; as also is the common occurrence of other anomalies (teeth, etc.) in association with lamellar cataract. In discussing the etiology of glaucoma, the author dissents from a dialysation theory for the origin of the intraocular fluids, and supports the older secretory theory on the ground of the proven circulation of the aqueous humour: but he makes no note that the more recent expositions of the former view insist that it also is not incompatible with the fact of a circulation of fluid and is in no way antagonistic to it. These, however, are small points, and they are mentioned because the book is good and is likely to become widely read among ophthalmological students, and will be welcomed into ophthalmological literature. The volume is admirably produced and well printed. The illustrations are numerous and valuable; the majority of them are photomicrographs and are excellent.

[1] *The Pathology of the Eye.* By Jonas S. Friedenwald, M.D., F.A.C.S. London: H. Kimpton. 1930. (Demy 8vo, pp. xx + 345; 253 figures. 21s. net.)

while only a few fail to convey the impression that is desired.

We welcome as a well-known friend the appearance of the sixth edition of Sir JOHN H. PARSONS's handbook on the *Diseases of the Eye*.[2] To the laudatory reviews which have appeared in these columns with each successive edition we would add little, with the exception of one thing: that, apart from being brought up to date by certain necessary alterations, it is little changed from its predecessor. The tendency for most standard works as they advance in years is to become larger and more complex. To do so with the present work would be to fall between two stools, and the result would be neither a textbook nor a handbook. In retaining its individuality and characteristics it still remains the best manual in ophthalmology in our language for the student or the practitioner.

THE CAPILLARY CIRCULATION.

THE Silliman Memorial Lectures at Yale for the year 1922 were given on *The Anatomy and Physiology of Capillaries*,[3] and published by Professor AUGUST KROGH of Copenhagen in the same year. Since then so much new work, especially that of Sir Thomas Lewis and Dr. E. M. Landis, has been done, that the present enlarged edition is in many respects a new book. It consists of fifteen chapters, an appendix on methods for the study of the anatomy and physiology of the capillaries, and a comprehensive bibliography. In the section on the structure of the capillary wall the author says that there is not any evidence that the endothelial cells are contractile, though they passively undergo changes in shape as the result of contraction of the muscular coat (Rouget cells and fibrils) of the capillaries. Heimberger's observations on the presence in living human subjects of arterio-venous anastomoses in the skin are described; these may contract so as to become closed, and must be regarded as extremely useful in maintaining the temperature of exposed parts. Knowledge of the innervation of the capillaries has been carried a good deal further since the first edition of this work, and Busch, working at Copenhagen, has confirmed Woollard's observations on this subject. The section on vascular reflexes has also been much expanded by inclusion of an account of Lewis's observations on the skin reactions and the H-substance allied to histamine.

In considering the complex reactions of the cutaneous capillaries reference is made to the so-called vaso-neurotic constitution characterized by the instability of the innervation of the vascular system, which varies considerably, not only from time to time, but from place to place. Even the same capillary may vary between normal parts, thus constituting true capillary aneurysms, Parrisius's figures of which are finely reproduced. The discussion of the changes in the permeability of the capillary wall has also been expanded as a result of Landis's recent findings, and leads up to the last chapter dealing with some applications of the physiology of the capillaries to complex processes in health and disease, such as the absorption of substances from the intestine into the blood, the formation of glomerular urine, and urticaria, inflammation, circulatory shock, and oedema.

PROGRESSIVE RELAXATION.

UNDER the title *Progressive Relaxation*[4] Dr. EDMUND JACOBSON, of the physiological department of the University of Chicago, presents to the medical profession the problems of neuro-muscular relaxation, and the therapeutic applications of rest. The whole subject is approached by means of laboratory investigations, which the author thinks more controllable than are clinical methods. Much of the painstaking work which has been done, and much that the author recommends his readers to undertake, would be impracticable under the ordinary conditions of general medical practice. The book loses in value because the advice to general practitioners is evidently given by one who understands little of the everyday routine in a general practitioner's life.

The earlier chapters deal with the therapeutic value of complete rest and the deleterious results of what is called "neuro-muscular hypertension." The clinical manifestations of such states as anxiety, pain, and toxic diseases as they affect the neuro-muscular apparatus, reflexes, and so on, are discussed in detail, to bring out the obvious need for relaxation of the muscles and complete rest as a desirable therapeutic agent. The technique of progressive relaxation, by practice on the part of the sufferer under the directions of the physician, is then fully dealt with, and the main point is that the patient is trained to remain "effortless," completely at rest, and so fully relaxed. The author emphasizes that the relaxed state is obtained only by practice. The middle part of his book deals at length with the physiological observations upon reflexes, conduction of the nervous impulse, stimuli of various kinds, etc., in published work by a host of other workers, past and present, to prove that in reality much of the "nervous patient's state" is accounted for by a heightened neuro-muscular tonus. Psychological factors related to relaxation are discussed, and lessened mental activities are noted as the patient becomes more "relaxed." The author meets the criticism that his method might be called hypnosis, and devotes a chapter to this argument in the later part of his work. Dr. Jacobson's very full discussion of muscle tonus and nervous regulation, quoting historical work and summarizing much of the recent observations, makes the book unnecessarily long.

The last three chapters, which deal with spastic oesophagus, mucous colitis, various medical conditions, and the general therapeusis of relaxation, are interesting to the clinician, but not very convincing, owing to the small number of cases treated and the incompleteness of the clinical records as compared with the minute details quoted in the physiological section of the book. All will be disposed to agree with the author's general conclusion that the methods discussed by him should be used, when possible, along with diet, drugs, and operative or other appropriate treatment for the good of the patient.

THE DISEASES OF INFANCY.

CHANGES in the regulations for the medical students in France have introduced a compulsory examination on the hygiene and diseases of the period of infancy, and largely to supply the information demanded by the authorities a new textbook has been written by numerous authors and edited by Professor A. B. MARFAN and Dr. H. LEMAIRE, under the title of A Précis of the Hygiene and Diseases of Infancy.[5] In an introduction Professor Marfan explains how he was instructed to arrange the course of lectures in these subjects for the Faculty of Medicine in Paris, and how he divided up the work. The lectures by his various colleagues and assistants have formed the basis for this new volume. After the usual introductory chapters on general lines, there follow sections on the diseases of the various systems, with interpolated chapters on syphilis and tuberculosis. Disorders of the newly born, infectious diseases, and congenital malformations are also fully treated, and the book concludes with a section on general therapeutics and on hygiene and preventive medicine. The period of infancy which is dealt with in this book is limited by the completion of the primary dentition, and throughout the various sections it is this period which alone receives attention. The result is a new outlook on children's diseases somewhere between that of the usual book on diseases of the newly born and that of the book on children's diseases in general. On the whole the teaching is clear and dogmatic, and for the most part controversial matter has purposely been omitted. Here and there, however, strictly French views are expressed without reference to criticisms from other countries, and Professor Marfan's own contribution on rickets is notably an exposition of his own special ideas, with a happy disregard for other people's contrary views. The section on congenital heart disease

[2] *Diseases of the Eye.* By Sir John Herbert Parsons, C.B.E., D.Sc., F.R.C.S., F.R.S. Sixth edition. London: J. and A. Churchill. 1930. (5½ × 8½, pp. viii + 678; 348 figures, 21 plates. 18s.)

[3] *The Anatomy and Physiology of Capillaries.* By August Krogh, Ph.D., LL.D., Professor of Zoo-physiology, Copenhag.: University. Second edition, revised and enlarged. New Haven: Yale University Press; London: Milford, Oxford University Press. 1929. (Med. 8vo, pp. xiii + 422; 101 figures. 18s. net.)

[4] *Progressive Relaxation.* By Edmund Jacobson, Ph.D., M.D. Chicago, Illinois: University of Chicago Press. 1929. (Med. 8vo, pp. xiii + 428; 69 figures. 22s. 6d. net.)

[5] *Précis d'Hygiène et des Maladies du Nourrisson.* Publié sous la direction de A.-B. Marfan et Henry Lemaire. Paris: J. B. Baillière et Fils. 1930. (8 r. 8vo, pp. 1169; 114 figures. 120 fr.)

is particularly good, with a careful description of the development of the heart as an introduction to the subject.

The general arrangement and production of this book are very satisfactory, although many radiograms have come out badly in the course of reproduction. A fairly complete index is included, which is all to the good, and rather unexpected in a work of this nature. Professor Marfan and his colleagues can be congratulated on a useful contribution to the literature of paediatrics.

CHEMISTRY OF THE ALKALOIDS.

Allen's Commercial Organic Analysis[6] is a very well known book. When first introduced it was intended to supply practising analysts with technical information and methods of analytical procedure. It has now appeared in a fifth edition, and in its general character has become a larger work of reference. The seventh volume is devoted almost entirely to the subject of alkaloids. The book has been prepared on the plan of dividing the subject-matter into sections, and allotting the preparation of each section to a writer chosen for his special knowledge in that sphere. There is thus an article on the aconite alkaloids by F. H. Carr, one on the cinchona alkaloids by Oliver Chick, another on the opium alkaloids by F. O. Taylor. In all, nearly forty drugs are dealt with in that manner. Tea, coffee, and cocoa are also included in the group, because caffeine and theobromine are now usually considered to be properly grouped among the alkaloids. The scheme of production, allowing as it does of individual freedom of treatment by different contributors, has obvious advantages, but it seems to result in some heterogeneity of style and composition. In the directions for the analysis of whole coffee beans there occurs (p. 378) the sentence: "Examine megascopically in order to detect foreign substances," but this only appears to mean "examine with the naked eye." On page 518 it is stated that "since the body soon becomes tolerant to cocaine, little or none may be found in the organs after death in the case of habitual takers." The sentence is set down as if it were a self-evident fact that acquired tolerance leads to the speedy disappearance of the alkaloid from the organs.

Extensive as are the researches on alkaloids that have been made by workers in various countries, it is remarkable how many gaps remain among items of information needed in everyday work. Should anyone want to know how long a hypodermic solution of cocaine hydrochloride could be kept without decomposition, or what heating for sterilization it would bear without chemical change, it would apparently not be easy to find authoritative answers. It is stated in "Allen" that many of the processes proposed for the assay of ipecacuanha are invalidated by the readiness with which emetine undergoes decomposition. That is only half the information that ought to be forthcoming. Analysts and others want to know what are the precise causes of decomposition, as well as the conditions under which the article is stable. This, however, is not due to failure on the part of the authors. Incredible as it may seem, many such facts of direct practical importance are hardly known. Those who have collaborated in the production of the present volume have done their work well. They have included all the published information, with bibliographical references to the source, as well as a large contribution from their own experience.

NOTES ON BOOKS.

DR. ABRAHAM LEVINSON'S valuable monograph on the *Cerebro-spinal Fluid in Health and in Disease* originally came out in 1919, and a second edition followed in 1923 (vide *British Medical Journal*, 1919, ii, 634; 1923, ii, 183). This work has steadily increased in size with the continued additions to knowledge, so that its third edition[7] runs to 386 instead of the original 231 pages, and the price has almost doubled. The short account of the Kahn test for syphilis, which does not require the haemolytic system (complement, amboceptor, and red blood corpuscles), has been written by Dr. R. L. Kahn, who is responsible for this test. The present edition fully maintains the position of Dr. Levinson's book as a most useful guide and source of reference.

MR. ARLETT'S *Course in Physics*[8] has been planned on a series of lectures delivered to first-year medical and dental students during the past six years. An attempt has been made to illustrate the methods and principles of physics by frequent reference to medical practice. There are sections on general physics, heat, light, electricity, an appendix of examination questions, and an index. In commenting on the criticism that there has been much perfunctory teaching of physics and chemistry in medical schools, the author states that it is now becoming possible to raise the standard of instruction, so that a syllabus can be closely adapted to the future requirements of the student in the more professional subjects of his curriculum.

The scholarship and lucid exposition that distinguish Professor ARTHUR THOMSON'S *Outlines of Zoology*[9] have already been referred to in this column. In the eighth edition there is a fuller consideration of the physiological aspect of the subject, and of the structure and development of certain types, such as the mud-fishes. Most of the supplementary illustrations have been drawn from specimens.

The forty-ninth volume of the *Transactions of the Ophthalmological Society of the United Kingdom*[10] embodies the text of various communications brought before the society during the session ended April, 1929, together with the reports of the transactions during 1922–29 of the North of England, Midland, and Irish Ophthalmological Societies, and of the proceedings of the Oxford Ophthalmological Congress, 1929. The volume is well illustrated by numerous diagrams and photographs, and by half a dozen plates, several of which are in colour.

The Health Resorts Section of the *Medical Directory*, edited by Dr. FORTESCUE FOX and published as *An Annual Guide to the Spas and Marine Health Resorts of Great Britain and Ireland and New Zealand*,[11] gives detailed information about medicinal waters, of health resorts of the British coasts, and of inland climatic health resorts. Lists of hydros, hotels, and other residential accommodation are appended.

PREPARATIONS AND APPLIANCES.

"DUO-FOCAL" SPECTACLES.

DR. HERBERT D. EVERINGTON (Sanderstead) writes: I have designed a new form of spectacles to which I have given the name "Duo-focals," and believe that these offer several advantages over ordinary bi-focal glasses. They consist of an ordinary pair of spectacles, having distance lenses mounted in the usual manner. Hinged to the outer and posterior part of the fronts are two smaller, semicircular *plus* lenses, which can be swung into position behind the distance lenses, thereby adding the convex lenses required to form correct reading glasses. The *plus* lenses, when not in use, are folded back, and lie along the inside of the arms of the spectacles. The change is made by the wearer without removing the glasses from the face; all he has to do is to pull the frames forward, when the forefingers quickly carry out the little operation. The reading lenses are mounted so as to allow bi-focal vision when in use. The distance lenses are preferably of the meniscus type, but the *plus* lenses may be flat. This combination offers the following advantages over ordinary "bi-focals": (1) a full field for distance, without restriction of the lower segment; (2) an ample field for reading, which is in the correct position, instead of a small field, placed inconveniently low; (3) good bi-focal vision, and, when this is no longer required, the avoidance of the danger that may result from looking through the wrong lenses. With advancing presbyopia, the *plus* lenses can be strengthened at frequent intervals, and more cheaply than with bi-focal lenses. The cost of the "Duo-focals" in the first place is no more than that of bi-focals, and it would often be less. They are made for me by Messrs. Curry and Paxton, 195, Great Portland Street, W.1.

THE HASTINGS POPULAR LECTURE.

SIR ANDREW BALFOUR ON "HEALTH AND EMPIRE."

THE Hastings Popular Lecture was delivered in the Great Hall of the British Medical Association House, Tavistock Square, on Wednesday evening, by Sir Andrew Balfour, K.C.M.G., C.B., director of the London School of Hygiene and Tropical Medicine. The chair was taken by Lord RIDDELL, who was supported on the platform by Dr. H. B. Brackenbury (Chairman of Council of the British Medical Association), Mr. Bishop Harman (Treasurer) and Mrs. Harman, Dr. G. F. Buchan, Mr. McAdam Eccles, Mr. E. B. Turner, Dr. E. Graham Little, M.P., and Mr. Stanley Duff, secretary of the National Conference of Friendly Societies.

Lord RIDDELL, in introducing the lecturer, said that in addition to his work in medicine Sir Andrew Balfour was a novelist of distinction. In one of his admirable novels the hero called upon a certain Sergeant Riddell to hold the lamp. That was the chairman's function that evening.

Sir ANDREW BALFOUR then gave the lecture on "Health and Empire," the text of which appears in this week's *Supplement*. It was admirably delivered, occupied just one hour—a remarkable feat of concentration—and the points were evidently appreciated by the large audience.

Dr. GRAHAM LITTLE, in proposing a vote of thanks to the lecturer, said that he had a special pride in doing so as the representative in Parliament of London University, for Sir Andrew Balfour was the director of the latest and one of the finest of the University schools, which now numbered forty-five. The school was a happy product of American and British zeal, for much of the money had been furnished by the Rockefeller Foundation. Sir Andrew had done wisely in pointing out the need for health education; nowhere was such education more needed than in Parliament. In conclusion Dr. Graham Little referred to the value of the school of which Sir Andrew Balfour was the head as a link of Empire, for students from all the Dominions and British possessions were attracted to its laboratories.

Dr. G. F. BUCHAN, medical officer of health for Willesden, seconded the vote of thanks, and spoke of the great importance of strong and progressive health administrations as a factor in maintaining the Empire. The question of health must not be considered as the exclusive responsibility of medical men. It was a matter in which the whole public should be informed, interested, and active.

The vote of thanks was heartily carried.

Sir ANDREW BALFOUR then replied to three questions which had been handed up from the audience. The first question was, "What is being done in Canada and elsewhere with regard to the registration of dairymen and butchers in order to prevent infectious disease?" In Canada and in many British possessions a great deal was being done along the lines of the registration of dairies. It was recognized that milk was an important source of infection, and when laws were framed in the Colonies concerning health matters they always embodied important regulations with regard to milk supply, including dairy registration. Even in such a remote island as Mauritius stringent regulations were in vogue. Canada, in its large towns like Toronto, was far ahead of most places in milk hygiene. With regard to butchers the case was rather different. Much more attention was paid to the question of butchers in the United States than in this country or in the British Dominions. Of course, the process of cooking generally eliminated any infection which the butcher might convey, but it was a disagreeable thing to bear in mind that butchers suffering from disease might handle meat.

The second question was, "Could some machinery be devised for acquainting European settlers in tropical countries with particulars as to medical research and facilities for treatment?" It was no doubt true, as the questioner added, that very many people abroad were not aware of the work of the London School of Tropical Medicine. The ideal thing would be that before people went out to the Tropics at all they should get authoritative information on the subject. Many of the medical departments in the different countries had taken up this matter and had gone in for extensive propaganda among the settlers, but often the settlers remained a little suspicious of people who were on hygienic errands. In Kenya, for example, among the farms, the medical officer might be greeted with the remark, "I know what you want. You want us to pull down these buildings and put up new ones. Well, we are not having any." Something was being done, however, in most of the large British colonies to educate not only the native but the European colonist. What more could be done it was difficult to say. The Tropical Diseases Bureau was always willing to answer inquiries, whether from lay or medical correspondents. But the question really resolved itself into the requirement that the local people should make known what facilities actually existed.

The final question was in the shape of a request to say something about the work of the Singapore Health Bureau. This bureau functioned under the auspices of the League of Nations. It had been founded at Singapore to collect and disseminate information about epidemic disease in the Far East so as to give early warning concerning outbreaks. Every year there was a meeting of sanitary administrators held at Singapore, and he believed that close contact was maintained with the Dutch authorities at Java and Sumatra; the Dutch had a great ideal of hygiene and the necessity of preventive medicine, and put some of our own colonies to shame by what they had done in that way.

Dr. BRACKENBURY, in proposing a vote of thanks to the chairman, said that among his many qualities Lord Riddell had two pre-eminently: he was full of public spirit, and he had an intense love for and desire to promote the welfare of hospitals and public health movements. Whenever anyone concerned with hospitals and the public health appealed for his assistance, he was rarely known to refuse. The British Medical Association much appreciated his kindness in this respect. It might not be known to the public how large a part of the energies of the Association was directed to research and the promotion of public health. As a fact, a very large sum of money, representing a considerable proportion of the Association's income, was devoted every year to advance the science and art of medicine. He wished to refer to one or two things that Sir Andrew Balfour had said. This question of health and Empire was not a merely historical question, with all its achievements and adventures belonging to the past; these activities were continually going on throughout the Empire, often in a dramatic form. That was brought home to him when, two years ago, he was in South Africa. At that time there had been a fairly rapid extension of plague through a large portion of the Union, and the great anxiety of the health authorities was to prevent the disease invading the Cape Province itself. The activities of the health department of South Africa were concentrated on one single pass in the mountains to prevent even one rat finding the only means of access open to it into the Cape. He also saw something of another service to which Sir Andrew Balfour had alluded—namely, the service in the Rand mines to preserve the health and promote the welfare of the natives who were employed there. A magnificent service it was, going on day by day, and effecting a wonderful change in the condition of affairs. Thousands of natives employed in these mines received daily benefit in this way. At the head of the service was a medical man who was also President of the Medical Association of South Africa (British Medical Association).

Mr. STANLEY DUFF seconded the vote of thanks to the chairman. They were all aware of Lord Riddell's many and diverse activities, but he doubted whether a more appropriate chairman could have been found for that occasion.

Lord RIDDELL, in reply, said that he thought he ought to pass a vote of thanks to the British Medical Association for inviting him to be present. Sir Andrew Balfour had effectively demolished the myth of the "good old days" to which so many people clung; they were in fact pestiferous old days, and for evidence on that point it was sufficient to read Chadwick's report on the state of England in 1834. Still, he found no pleasure in reproving his ancestors, and no doubt some eminent lecturer, speaking in that hall a hundred years hence, would equally complain of the ignorance and laxity of the people of 1930.

British Medical Journal.

SATURDAY, MARCH 15TH, 1930.

RESEARCH PHYSICIANS.

EARLY in February the Biochemical Society, together with many members of the Physiological Society, gave a banquet at the Hotel Victoria to the four Nobel Prize Laureates in medicine and chemistry for the year, of whom two—Sir Frederick Gowland Hopkins and Professor A. Harden—are British. Half-way through the dinner a figure shaped in transparent ice was borne in aloft and placed before the Swedish Minister and the representatives of science at the high table. The chef, seeing "Medicine" on the front of the menu card, had devised an orthodox physician, in frock-coat and with binaural stethoscope in his ears. The effigy, rapidly melting, was soon taken away. But the figure, vanishing, and disregarded by the biochemists and physiologists at their meeting to honour work done in medical science, was an emblem of what is at the heart of the difficulties discussed by Sir Thomas Lewis in his paper which we publish this week at page 479.

The science of medicine is being rapidly advanced by those who have left all contact with patients, and work exclusively in the laboratories of physiology and pathology. The practice of its art becomes yearly more intricate, as the advance of knowledge from all sources adds to the burden of detailed information which the consultant and teacher in general medicine must carry for his work. His intellectual leisure is as much curtailed as is that of the medical student, whose bondage to the ever-increasing medical curriculum has awakened pity. It grows ever harder for the clinician to emulate the scientific achievements of his great predecessors in the last century, who made discoveries by relatively easy methods of observation. The surface yield is nearing exhaustion, and deeper methods of working, with complex machinery and sustained effort in its use, are now required. Must the clinician, in face of these difficulties, soon renounce the pride of his intellectual heritage, and hand over to his own offspring, the physiologists and pathologists, the great duty of advancing knowledge? Lewis answers emphatically, "No, provided that the difficulties are faced and the pathway through them clearly defined." The problems peculiar to surgery are not considered in his argument. In the field of medicine he draws very clearly the distinction between two activities of the physician's mind: the one concerned with diagnosis and care of the individual sick man; the other seeking to advance knowledge of the laws that co-ordinate the phenomena of disease. Diagnostic work, the virtue of the good clinician, is in no danger of decay in Britain. Medical research—the instrument of progressive medicine, as it is styled by Lewis—has in our country made two great advances in the present century, one in the field of heart disease, the other in new knowledge of the uses of vitamins. These forward movements did start from a basis of diagnostic work that defined the clinical problems, but the essential advances came through the *experimental* method appropriate to laboratories. It is the relationship of clinical workers to the use of such laboratory methods that Lewis is discussing in his analysis of the future of progressive medicine, and the views developed by him in this connexion lead to conclusions with which we find ourselves in agreement.

All thinkers will admit that no one but a clinician, and a clinician of experience, can do the work of describing the natural history—that is, the ordinary progress—of a disease, with its complications and after-effects, as they are actually seen in man. To the clinician belongs the whole field of the so-called clinical entities, and his will always be the appropriate task of testing means whereby these conditions may be quickly identified, and pushing back the possibility of diagnosis earlier and earlier to the manifestations which lie at the very beginnings of the disease, where a happy chance may allow precaution in treatment almost to join hands with prevention. It is not denied that research by physicians who are, first and foremost, diagnosticians may continue to yield important results, as it has done in the past. But Lewis insists that diagnosis and clinical observation do differ essentially from the method of experimental medicine. The pathways diverge, and no man can hope to remain for long a master of both routes. The technique of experimental medicine grows more complex; its associations with physiology and pathology are now so intimate that the time required for their comprehension cannot be found by the clinician, who must by daily experience maintain his general skill in diagnosis. Even more important than these difficulties is the distinction that Lewis reveals in the mental discipline of the two forms of medical work. Training in diagnostic skill makes for quick decisions, and it demands a memory abundantly stored with wide clinical experience. Experimental research cares less for immediate diagnosis of a malady, and it can neglect the laborious clinical training that alone gives such powers of diagnosis. It may delay judgement until the evidence is fully and satisfactorily collected; and it will therefore insist on proof in a scientific form that is unattainable in the immediate demands for decision and action characterizing curative medicine. An insistence on rigid proof and a dislike for the hasty airing of untested hypothetical explanations make up the mental atmosphere of workers in the scientific laboratories of physiology and pathology. This mental environment and the appropriate conditions for study of the problems of research can be, and are, reproduced in clinical medicine, but only by recognizing that between the two main bodies of workers—the diagnosticians and therapeutists on the one hand, and the non-clinical laboratory workers on the other—there is a gap which demands an intermediate group—clinicians trained to rigid scientific methods of thought and observation, who will inquire into problems, on the living patient, of which the physiologist or pathologist might not comprehend the importance, and which in any case he could not study for lack of clinical knowledge. Such workers, according to Lewis's reasoning, should not seek the wide experience of disease required for consulting practice; they must make their choice early for scientific research, and look to a career neither as pathologists nor as general consultants, but as whole-time research physicians, each in a restricted field of clinical experience. If such a choice is to be made it is plain that the career must lie as a practical possibility in front of the man. In it he will soon have lost his chance of fitting himself for the customary alternative of consulting practice; and his future must be assured on the path which he has chosen.

Two questions therefore arise, and their right answer is a matter of deep importance to the progress

of British medicine. Does the further development of scientific medicine require that the research physician be so unhesitatingly separated from the diagnostician? We think that a strong case has been stated for this view. Secondly, the need for workers in this relatively novel group being granted, how can the opportunity of hospital beds and the financial provision be obtained for them? The recently published report of the Medical Research Council for 1928–29[1] devotes an entire section to a careful analysis of the position of clinical research in Britain. This reasoned judgement—and it is one that merits deep attention on account of the experience that the Council has gained in the years during which it has been seeking to foster research on medical problems—is that men of the intermediate group are emphatically needed. In 1916 the Council had established Sir Thomas Lewis in a research post at University College Hospital of the type which he is now describing; and the conspicuous success of that experiment has now led the Council to announce formally its intention of providing stable careers for other men who may elect to follow that lead in clinical research. That encouraging guarantee of increased financial support will be an important factor in aiding recruitment for this band of workers. With regard to the needed opportunity of hospital beds the Council cannot make any direct provision. It will naturally occur to many of our readers that this difficulty might be overcome, in London at any rate, by some association with the five medical units that have about sixty beds apiece allotted to them at different metropolitan medical schools. The primary duty of these units is the instruction of medical students, and their position in that respect was admirably discussed by Sir Wilmot Herringham in the *British Medical Journal* of September 29th, 1923. General teaching makes it impossible that their directors should detach themselves from the entanglement of general diagnostic work. But it was intended that the units should also be a place of training for men who might later devote their powers to research. In this respect the scheme was incomplete, for there was no life career open in clinical research. The units send their trained assistants either into pure laboratory work or into the consultants' world of diagnostic medicine; and in the one direction no less than in the other the helm immediately points away from the course of clinical research. The report of the Medical Research Council and Sir Thomas Lewis's clear analysis should go far to convince those who have at heart the progress of medicine in Britain that some posts must be created for research physicians.

THE HASTINGS LECTURE.

THE Hastings Popular Lecture, which was delivered by Sir Andrew Balfour in the Great Hall of the British Medical Association on Wednesday, and is printed in this week's *Supplement*, forms the third of a series of lectures instituted in honour of Sir Charles Hastings, the founder of the Association. These lectures are addressed to the public rather than to the profession, and therefore their subject-matter will probably always to some extent appear lacking in novelty to the medical man. They serve, however, as a reminder that the objects for which the Association exists are not limited to the maintenance of professional interests and the furtherance of medical discovery, but include also an endeavour to enlighten the public on matters relating to health—an object the importance of which has become increasingly realized in recent years. Because of its world-wide influence, the British Medical Association is the best agency for the dissemination of such knowledge, though the daily press would be a valuable adjuvant if the choice of fit subject-matter could be ensured. It is only natural that a lecture instituted in memory of Charles Hastings should carry the mind back to the early years of the last century and move us to inquire what were the features in the Association he founded which have rendered it so permanent and explain its phenomenal growth. The records of the time show that, apart from the sound ideals of the founder, existing circumstances rendered his institution peculiarly fitted to further the movement then taking shape for the betterment of the profession; and for evidence of the need of such a movement one has but to study the condition and status of the profession a hundred years ago.

In his discourse Sir Andrew Balfour endeavoured to convey to the public some idea of the saving in life and treasure which has accrued to the British Empire from the application of the knowledge gained during the last hundred years. Any approach to a complete estimate is evidently impossible; the sum total of the benefits derived is large beyond the powers of computation, but the lecturer adduced examples of losses sustained in the earlier years of the period, before the modern discoveries of medical science were available, using these as an index of what would doubtless be sustained at the present time in the absence of medical intervention. Briefly, he refers to the scourges of cholera and relapsing fever to which we were exposed in the sixties, to the ravages of scurvy, the decimation caused by epidemics of yellow fever, typhoid, and plague, and to the appalling loss of life from malaria. These and other instances cited serve to indicate the magnitude of the undertaking which medical science was called upon to face, and which it faced with wonderful success. These diseases are now under control, or would be so if the recommendations of the medical profession could be fully complied with by the authorities responsible for the public health; and it may be truly said that the whole aspect of the British Empire as regards the incidence of disease has been transformed. The means which have wrought this change are discussed by the lecturer under the three headings of hygiene, medicine, and organization, or the practical application of remedial measures. As director of the London School of Hygiene and Tropical Medicine he views with pardonable jealousy a seeming tendency of Medicine to claim the lion's share of credit for recent progress; the honourable part played by Hygiene will, however, surely be gladly admitted by all. The change for the better in the matter of hygiene began in this country about the middle of the last century, when the enthusiasm and unremitting labours of Edwin Chadwick and his disciples laid the foundations of sanitary science. They preached the gospel of cleanliness, and, as bearing on the importance of public enlightenment, the lecturer notes that the acceptance of their teaching by those in high places and by the populace, even when repeated outbreaks of cholera came to the assistance of the reformers, was not easily effected, and that it needed the most dogged determination to achieve a sanitary revolution. When the efficacy of public health work was finally recognized in Great Britain, and the ultimate responsibility placed on the Government, the Dominions and Colonies were not slow to follow the lead of the Motherland.

and in some matters they are now ahead of the Old Country. However, the efforts of both physician and hygienist were beset with difficulties and obscurities until their path was illuminated by the light of science, although the application of the principles of sanitation accomplished much in the way of prevention and amelioration. It was not until the dawn of the era of tropical medicine, with its surprising revelations, that any considerable advance was made either from the purely medical or the purely sanitary standpoint.

Of the great achievements of that era our readers need no reminder—of Bruce and Mediterranean fever and trypanosomiasis, of Theobald Smith and Texas fever, of Manson and filariasis, of Ross and malaria, of Gorgas and yellow fever; it is probable, however, that the public has but a very imperfect knowledge of the magnitude of the benefits they derive from these and similar discoveries. It cannot be considered unimportant that the public should be informed on such subjects, especially as the practical realization of these benefits depends largely on its co-operation and that of the public authorities, without which the efforts of medical men are impotent. This co-operation has for the most part been unstintingly accorded, and too much praise cannot be given to our health authorities for the work they have already accomplished. But Sir Andrew Balfour has felt constrained to "report it as deficient" (to use the expression of Francis Bacon) in certain particulars. For example, he states that as an Empire we have not done our best to cope with malaria, although it is admitted that the difficulty is enormous. Here and there Ross's method of dealing with the disease has been pursued with advantage, and remarkable results have been obtained; but the method has in many places been neglected or not applied with the thoroughness and energy which ensures success. Similarly, in the matter of hygiene due consideration does not appear to be accorded to our merchant seamen, and the conditions under which they serve afloat compare unfavourably with those obtaining in the ships of other maritime nations. On the whole, however, if we cast our minds back ninety-eight years, to the time when Charles Hastings founded the British Medical Association, there will be found abundant grounds for congratulation on the progress to be credited to the account of medical and sanitary science.

PAINFUL SPASMODIC FLAT-FOOT.

THE discussion on spasmodic flat-foot, at a well-attended meeting of the Section of Orthopaedics of the Royal Society of Medicine, on March 4th, fully justified the choice of the subject by the council. Mr. S. A. S. Malkin, in his opening paper, thoroughly explored his subject-matter, which, as he remarked, had long been neglected as the ground for a full-dress debate. All orthopaedic surgeons, and most other surgeons, are familiar with the type of case which occurs in weedy, overgrown adolescents, with clammy feet and rather low vitality. As the speakers in the discussion agreed, such cases are less common than they were some years ago, when lads on leaving school were more commonly obliged to work for long hours carrying burdens too heavy for their immature frames. Such patients were very often grocers' errand boys and the like. The introduction of the carrier tricycle and the motor bicycle has relieved the younger generations of the burdens which oppressed their foregoers of thirty and more years ago, and adult porters are becoming rarer and rarer, till a porter's knot is unknown except in some river and dockside localities. It was generally agreed at the meeting that the spasm of the abductors in this form of flat-foot is to be regarded as secondary to the joint lesion, whether the latter be simply overstretching of ligaments or actual synovitis. As Mr. Malkin pointed out, the group of muscles in which spasm is observed, the peronei and extensors of the toes, are the weaker of the two groups concerned with movements of the foot, and some surprise might be felt that they should prevail; but it must not be forgotten that the position of extreme eversion is the only one the adoption of which obviates the necessity of movement in the transverse tarsal joints in locomotion. This may be seen in cases of rheumatoid or other obvious arthritis such as occurs in elderly waiters, whose shuffling gait is largely due to disuse of the everted metatarsus in walking, and instinctive avoidance of any pressure upon it. Treatment has not altered in essentials for the last thirty years or more, except that massage and re-education of muscles have come to have a more important place. The immediate results have been generally favourable, but most speakers were agreed that complete cure was seldom attained. The operation of removal of all or part of the navicular bone, practised by Lund of Manchester, has been abandoned and almost forgotten by post-war orthopaedic surgeons, and since Lorenz of Vienna declared a good many years ago that the spasm was a reflex phenomenon due to synovitis in the joints between the two rows of tarsal bones, which spasm could be relieved by the injection of cocaine into those joints, no striking innovation in treatment has come to the front. Mr. Trethowan, however, in this discussion gave his hearers much food for reflection when he rather bluntly declared that in his experience in all these cases, with very few exceptions, synovitis and spasm were but manifestations of intoxication from remote septic foci, and that the offending focus was almost invarably situated in the tonsil, and its removal followed by disappearance of symptoms. So constant was this sequence of events that he now preferred to call these feet not "spasmodic flat feet" but "tonsil feet." That septic foci in tonsils, teeth, or elsewhere may well be the origin of synovitis or general arthritis has long been an accepted postulate, and the manifestation of the disease in the tarsus may be due to the well-known selective action of the poison, which finds in damaged tissue a favourable site for development. It is true that septic tonsils are very common and spasmodic flat-foot comparatively rare, but it may be that there is a tertium quid as yet unknown, the presence of which is necessary for the production of the tarsal lesion. Wider and longer experience is needed before this pathology will be accepted definitely, and we hope that others as well as Mr. Trethowan will explore further the line of research on which he has been working. But the patient who has been suffering from painful spasmodic flat-foot will care little for pathology or septic foci as such. What he asks for is cure. Can we give him a restitutio ad integrum? Nearly every speaker in the discussion agreed that it would be necessary after active treatment for the patient to wear some support for the weakened feet and muscles, varying from a wedge sole to steel instruments extending to the calf, if he is to follow any avocation necessitating much standing or any weight-bearing. But to our mind the best advice that can be given involves the abandonment of such occupations. If the errand boy can be apprenticed to a tailor and learn to sit cross-legged upon a board, that mere posture will correct tendencies to valgus of the foot and ankle, and at the same time favour the resumption of postural tone in the formerly over-stretched adductors and flexor muscles. This and other sedentary occupations, especially if they are not associated with much beer, may be confidently recommended to the sufferers from painful splay-foot.

POST-VACCINAL ENCEPHALITIS.

"THE price of compulsory vaccination on a scale likely to save lives must be paid in lives." This conclusion, drawn by Professor Major Greenwood from a study of data bearing on the vaccination problem and presented in his paper summarized at length in our issue of March 1st (p. 398), derives most of its force from the appearance, at a time when the prevalent small-pox is mild and but rarely fatal, of a post-vaccinal encephalitis which is fatal in some 50 per cent. of cases. Professor Greenwood's statement does not imply, and he does not intend it to imply, that vaccination does not in fact protect against small-pox; but the trend of opinion about the desirability of compulsory vaccination is bound in some measure to be determined by the extent to which it may be found possible to control, or to prevent completely, the incidence of a dangerous post-vaccinal complication. Little progress in this direction may be expected while next to nothing is known about the etiology of post-vaccinal encephalitis. So far, however, as Dr. Simon Flexner points out in an interesting paper on post-vaccinal encephalitis and allied conditions, recently published in the *Journal of the American Medical Association* (February 1st, p. 305), there has been a great deal of conjecture and hypothesis on this subject, but only very little scientific observation. Vaccinia virus itself has been regarded by some as the offending agent; or vaccinia virus introduced into the skin by vaccination has been held to rouse into activity a second micro-organism already present, though latent in the body. Finally, from the fact that the condition has a fixed incubation period of about ten to thirteen days after vaccination, coinciding with the period during which antibody formation reaches a maximum, Glantzmann and others have suggested that the first action of the vaccinia virus is to sensitize nervous tissue, after which, at the height of antibody production, an allergic reaction occurs, producing a kind of "shock," which ushers in the encephalitic process. This view obviously fails to account for the rarity of post-vaccinal encephalitis. The latent ultra-microscopic virus hypothesis implies the existence of a synergic process unknown to pathology; moreover, suggests Dr. Flexner, the virus itself must be conceived not only to have appeared suddenly in the world but to have become somehow widely disseminated, while having only a capricious activity. It may be added that animal inoculations carried out with nervous tissues and cerebral spinal fluid have so far failed to yield results supporting either this or any other theory of the cause of post-vaccinal encephalitis. That vaccinia virus itself may sometimes act as the provocative agent of encephalitis has been held by a number of pathologists. McIntosh and Turnbull were able in two cases to recover vaccinia virus from the brain in fatal cases, but this and similar findings do not prove that the virus was responsible for the lesions. Observations on man and experiments in animals have shown that vaccination is not a local process, but a general infection with, as a rule, a single local lesion. In rabbits, for example, the virus may be found in the blood, internal organs, and buccal mucosa, from the second to the tenth day after vaccination. The brain of the rabbit, however, is resistant to directly injected vaccinia virus. Only after adaptation by organ to organ passage does the virus become effectively pathogenic, and then the response is of the nature of a fulminating infection in which the lesions are more meningitic than encephalitic. The central nervous system tends to escape focal lesions from generalized vaccinia, even when the skin, mucous surface, and internal viscera are widely affected. So far, then, as the available data can be interpreted, it appears that vaccinia virus is not the specific instant of the encephalitis that attends vaccination. The complication arises in man only once in several thousand vaccinations; there would therefore seem to be much reason in Dr. Flexner's pessimistic view that unless accident intervenes, or some certain method of evoking the condition experimentally can be discovered—for example, by reproducing it in animals—the search for the etiology of post-vaccinal encephalitis, and thence for a method of controlling it, is likely to be protracted.

HYGIENE OF CREWS' SPACES ON MERCHANT SHIPS.

WE are glad to note that the proper body to take action in this matter—namely, the Association of Port Sanitary Authorities—has now made a definite move in the right direction. An important deputation from this organization, consisting of the president, Alderman Mrs. L. M. Foster-Welch (Southampton), Councillor J. E. Jones (Bristol), the honorary solicitor, Mr. W. R. Platts, with the port medical officers of London, Manchester, Newport, and Dover, attended at the Board of Trade offices on March 6th, to explain the attitude taken up by the association on the question of insanitary housing of seamen on British ships, and to suggest appropriate remedies. Dr. A. Vernon Davies, M.P., accompanied the deputation. Mr. A. J. Foley, assistant secretary, represented the Board of Trade, and had with him the heads of the various sections of the Marine Department. We have no details of what took place, but we understand that the speakers put forward a strong case for Government intervention, and that it was well received. They had certainly plenty of available material to draw upon. The question has been a sore one with port medical officers for years, and has been dealt with on many occasions in their annual reports. The position is somewhat as follows. Though seamen and firemen are housed separately, it is the usual practice to crowd each section into a common room with a cubic capacity equivalent to 120 cubic feet of space per man. A separate messroom can be provided at the expense of the air space in the sleeping room, but the ordinary practice is to use the common room for sleeping, eating, resting, recreation, and storage of clothing and of food. In the majority of British ships these living quarters are still placed in the most dangerous, uncomfortable, and unhealthy position—namely, the forecastle—where, even in moderately rough weather there is such a buffeting from head winds and seas that ventilators and stovepipes have to be unshipped, ports closed, and deadlights screwed down; there is also a considerable amount of wet and damp from leaks, soaked clothes, oilskins, or condensation water. With crews' quarters of this type it is quite unusual to find provision for isolating cases of infectious disease. By a simple rearrangement and by provision of more air space all these unhygienic conditions could be avoided, but unfortunately no one has the power to order the necessary rearranging. All that the Board of Trade can enforce is the 120 cubic feet, firm construction, protection from weather and sea, proper means of lighting and ventilation, and freedom from bilge and cargo effluvia; all that the port medical officer can do is to serve Public Health Act notices for abatement of nuisances arising within the legalized space. Yet there are British shipowners who voluntarily provide their sailors and firemen with two-berth or three-berth cabins amidships or aft, with separate messrooms, drying rooms, oilskin lockers, washhouses, baths, and hospitals, and all these amenities are compulsory on the ships of certain other countries. On the other hand, new ships are being built with crews' quarters in the old position and of the old type. In our opinion the Government of the day made a great mistake in not taking up this question immediately after the war, when shipping was depleted and trade was booming. Ten years have already been lost, and an enormous number of new un-

hygienic ships must have been launched during that period. We venture to trust, however, that the present Government will take its courage in both hands and produce the necessary legislation. It is well known that the Foreign Secretary was particularly enthusiastic in this direction before the last General Election.

RHEUMATIC PERICARDITIS IN CHILDHOOD.

AN interesting example of the close criticism to which accepted views about juvenile rheumatism are being subjected is found in an article on rheumatic pericarditis in childhood contributed by Professor Leonard Findlay, with Dr. J. W. Macfarlane and Dr. Mary Stevenson, in the current issue of the *Archives of Disease in Childhood*.[1] In the first place these authors bring forward evidence to prove that they are justified in dealing with pericarditis as distinct from involvement of the heart as a whole. Despite the statements of great authorities of the past—for example, of Sturges and Cheadle—in support of the view that in rheumatic involvement of the heart there is a pan-carditis, the Glasgow workers point out that in thirty post-mortem examinations of children who had died from all forms of rheumatic heart disease, they found implication of the pericardium in only 50 per cent. Furthermore, having established that pericarditis can be considered apart from involvement of the heart as a whole in rheumatism, Professor Findlay and his associates find themselves at variance with accepted views of its relation to other rheumatic phenomena. It is generally held that there is a close relation between chorea and pericarditis, a view often summarized in the phrase that chorea *plus* nodules *means* pericarditis. The authors, indeed, include in their paper an interesting historical survey of the literature dealing with the association of pericarditis and chorea, but when they analyse their own cases they show that the association is not very close. They have taken the records of 51 cases of rheumatic pericarditis admitted to the Royal Hospital for Sick Children, Glasgow, between the years 1915 and 1928. In 4 of these a heart lesion was the only manifestation of rheumatic mischief; in 2 cases pericarditis was the sole cardiac sign, there being no evidence of endocarditis either at the time of the acute illness or subsequently. In 44 out of the 51 patients there was a definite rheumatic arthritis as part of the syndrome; in 17 this arthritis preceded by a definite period the appearance of pericarditis, while in 26 the pericarditis ensued during an attack of arthritis. Of the cases with chorea and pericarditis, 15 in all, there were only 2 in which chorea was the sole rheumatic manifestation other than the cardiac involvement. In the other cases with chorea, arthritis was also a feature of the rheumatic trouble. Thus, far from a frequent association of chorea with pericarditis, the authors found that in only two cases did these conditions so coincide that there could be any question of considering one as a complication of the other. On the other hand, their analysis suggests that arthritis is the almost invariable precursor or accompaniment of pericarditis. This conclusion is important, if it can be supported from other centres, for the difficulty of explaining the association of pure chorea and pericarditis has long been recognized. While the substitution of arthritis for chorea does not solve the whole problem, at least it may be acknowledged that in both conditions there is inflammation of a serous membrane. On the other aspects of rheumatic pericarditis the Glasgow workers are generally in agreement with accepted views. Thus, with regard to the gravity of the condition, they found that 26 of their 51 patients died, while most of the surviving 25 show evidence of cardiac disease and disability. Curiously enough, their figures for sex incidence reveal a predominance among females, though a male majority is usually recorded. The incidence of nodules—in 6 of the 51 patients—is lower than that recorded in other investigations. The study of the cases here presented is interesting from many points of view, and while the conclusions will not be accepted in their entirety their unorthodox nature will stimulate and refresh.

BIOLOGICAL STANDARDIZATION OF DRUGS.

THE fourth annual report of the pharmacological laboratory of the Pharmaceutical Society contains a summary of the results of a number of investigations which are of great interest to the medical profession. A considerable part of the biological standardization carried out in this country has been centralized in these laboratories under the direction of Dr. J. H. Burn, and as a result it is possible to obtain information about the amount of variation in the material tested. These results furnish striking evidence of the importance of biological standardization. For example, the result of testing nine samples of strophanthin was to show that the strongest had two and a half times the physiological activity of the weakest. Since strophanthin is intended for intravenous injection, it is obvious that variation on such a scale is a matter of serious importance. It is fairly generally known that liquid extract of ergot made according to the directions of the current *British Pharmacopœia* is inert, but the report shows that the method laid down in the United States Pharmacopœia is also unsatisfactory. This method produces an active preparation, but unfortunately half the activity is lost within two or three months, even under the best conditions of storage. The problem of preparing a satisfactory extract of ergot is therefore still unsolved. Tetra-iodophenolphthalein sodium is a drug which is finding increasing use, but the toxic effects it sometimes produces are a serious problem. Toxicity tests have shown that some samples of the drug are nearly 50 per cent. more toxic than others. The need for the biological standardization of certain drugs is now generally recognized, but these examples indicate new applications for this method. The increasing use of potent drugs in doses sufficient to produce a full physiological effect seems likely to reveal an increasing need for supplementing tests of chemical purity with tests for physiological activity. The second part of the report deals with the work of the nutrition department, which has conducted a large number of routine tests, chiefly for the estimation of the vitamin A and D content of preparations. Quantitative estimations have yielded the interesting result that the best samples of milk have only a five-hundredth the vitamin D content of a good average sample of cod liver oil. The antirachitic action of 20 drops of cod liver oil is therefore equivalent to that of at least a pint of good milk.

THE Lumleian Lectures before the Royal College of Physicians of London will be given by Dr. Carey F. Coombs at the College, Pall Mall East, S.W.1, on March 26th, 25th, and 27th, at 5 p.m.; the subject is syphilis of the heart and great vessels. Any member of the medical profession will be admitted on presentation of visiting card.
